Abstract of JP
2005073276 (A)

PROBLEM TO BE SOLVED: To provide a method and apparatus for reporting buffer status information of a buffer stored with packet data to be transmitted by a user terminal for a scheduling assignment of an uplink packet data service, in a mobile telecommunication system supporting uplink packet data service. ; **SOLUTION:** The terminal stores packet data, having a priority corresponding to a plurality of priority queues having inherent priorities and relating to at least one service, and transmits buffer status information, containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues. Herein, the terminal inserts the buffer status information into a header part of a protocol data unit (PDU) for the uplink packet data service, inserts the packet data into a payload part of the protocol data unit, and then transmits the protocol data unit. ; **COPYRIGHT:** (C)2005 JPO&NCIP

(54) 【発明の名称】 移動通信システムで上りリンクパケット伝送のためのスケジューリング割当方法及び装置

(57) 【要約】

【課題】上りリンクパケットデータサービスを支援する移動通信システムで、該上りリンクパケットデータサービスのスケジューリング割当のために使用者端末が伝送しようとするパケットデータを格納しているバッファのバッファ状態情報を報告する方法及び装置を提供する。

【解決手段】端末は、固有の優先順位を持ち、少なくとも一つのサービスに関連する複数の優先順位キューに、該当する優先順位を持つパケットデータを格納し、これらの優先順位キューのキュー識別子とこれらの優先順位キューに格納されているパケットデータの量を表すバッファペイロード情報を含むバッファ状態情報を伝送する。このときに、端末は、逆方向パケットデータサービスのためのプロトコルデータユニット(PDU)のヘッダー部分にバッファ状態情報を挿入し、プロトコルデータユニットのペイロード部分にパケットデータを挿入して伝送する。

【選択図】図11

【特許請求の範囲】**【請求項1】**

上りリンクパケットデータサービスを支援する移動通信システムにおいて、前記上りリンクパケットデータサービスのスケジューリング割当のために、使用者端末が伝送しようとするパケットデータを格納しているバッファのバッファ状態情報を報告する方法であって、

a)固有の優先順位を持ち、少なくとも一つのサービスに関連する複数の優先順位キューに、該当する優先順位を持つパケットデータを格納するステップと、

b)これらの優先順位キューのキュー識別子とこれらの優先順位キューに格納されているパケットデータの量を表すバッファペイロード情報とを含むバッファ状態情報を伝送するステップと、

を含めてなることを特徴とする方法。

【請求項2】

前記ステップb)は、

前記逆方向パケットデータサービスのためのプロトコルデータユニット(PDU)のヘッダー部分に、前記バッファ状態情報を挿入し、前記プロトコルデータユニットのペイロード部分に、前記パケットデータを挿入して伝送することを特徴とする請求項1に記載の方法。

【請求項3】

前記バッファ状態情報は、

前記複数の優先順位キューのうち、格納されたデータが存在する少なくとも一つの優先順位キューを表すキュー識別子マップと、

前記キュー識別子マップが表す少なくとも一つの優先順位キューの識別子と、

前記キュー識別子マップが表す少なくとも一つの優先順位キューに格納されたデータの大きさと、

からなることを特徴とする請求項2に記載の方法。

【請求項4】

前記ヘッダー部分は、向上した逆方向専用伝送チャネル(EUDCH)のためのMAC(Media Access Control)シグナリングヘッダーであることを特徴とする請求項2に記載の方法。

【請求項5】

前記使用者端末にサービスを提供する基地局から、前記バッファ状態情報に対応するスケジューリング割当情報を受信し、該スケジューリング割当情報に基づき、前記複数の優先順位キューから優先順位の高いパケットデータを優先して読み出して伝送するステップをさらに含むことを特徴とする請求項1に記載の方法。

【請求項6】

上りリンクパケットデータサービスを支援する移動通信システムにおいて、使用者端末が前記上りリンクパケットデータサービスのスケジューリング割当のためのスケジューリング情報を報告する方法であって、

前記逆方向パケットデータサービスのためにヘッダー部分とペイロード部分とから構成されたプロトコルデータユニットを生成するステップと、

前記ヘッダー部分に前記スケジューリング情報を挿入し、前記ペイロード部分に、前記逆方向パケットデータサービスのためのパケットデータを挿入して伝送するステップと、

を含むことを特徴とする方法。

【請求項7】

前記スケジューリング情報は、

固有の優先順位を持ち、少なくとも一つのサービスに関連する複数の優先順位キューを表すキュー識別子と、これらの優先順位キューに格納されているパケットデータの量を表すバッファペイロード情報と、を含むことを特徴とする請求項6に記載の方法。

【請求項8】

前記バッファペイロード情報は、
前記複数の優先順位キューのうち、格納されたデータが存在する少なくとも一つの優先順位キューを表すキュー識別子マップと、
前記キュー識別子マップが表す少なくとも一つの優先順位キューの識別子と、
前記キュー識別子マップが表す少なくとも一つの優先順位キューに格納されたデータの大きさと、
からなることを特徴とする請求項7に記載の方法。

【請求項9】

前記ヘッダー部分は、向上した逆方向専用伝送チャネル(EUDCH)のためのMAC(Media Access Control)シグナリングヘッダーであることを特徴とする請求項6に記載の方法。

【請求項10】

前記使用者端末にサービスを提供する基地局から、前記スケジューリング情報に対応するスケジューリング割当情報を受信し、該スケジューリング割当情報に基づき、優先順位の高いパケットデータを優先して伝送するステップをさらに含むことを特徴とする請求項7に記載の方法。

【請求項11】

上りリンクパケットデータサービスを支援する移動通信システムにおいて、前記上りリンクパケットデータサービスのスケジューリング割当のために、使用者端末が伝送しようとするパケットデータを格納しているバッファのバッファ状態情報を報告する装置であって、

同じ優先順位を持ち、少なくとも一つのサービスに関連するパケットデータを格納する複数の優先順位キューと、

これらの優先順位キューのキュー識別子と、これらの優先順位キューに格納されているパケットデータの量を表すバッファペイロード情報とを含むバッファ状態情報を生成するスケジューリング制御器と、

前記バッファ状態情報を伝送する送信部と、
を含めてなることを特徴とする装置。

【請求項12】

前記送信部は、

前記逆方向パケットデータサービスのために、ヘッダー部分とペイロード部分とから構成されたプロトコルデータユニット(PDU)を生成し、前記ヘッダー部分に前記バッファ状態情報を挿入し、前記ペイロード部分に、前記優先順位キューから読み出したパケットデータを挿入するプロトコルデータユニット生成器を含むことを特徴とする請求項11に記載の装置。

【請求項13】

前記バッファ状態情報は、

前記複数の優先順位キューのうち、格納されたデータが存在する少なくとも一つの優先順位キューを表すキュー識別子マップと、

前記キュー識別子マップが表す少なくとも一つの優先順位キューの識別子と、

前記キュー識別子マップが表す少なくとも一つの優先順位キューに格納されたデータの大きさと、

からなることを特徴とする請求項12に記載の装置。

【請求項14】

前記ヘッダー部分は、向上した逆方向専用伝送チャネル(EUDCH)のためのMAC(Media Access Control)シグナリングヘッダーであることを特徴とする請求項12に記載の装置。

【請求項15】

前記スケジューリング制御器は、

前記使用者端末にサービスを提供する基地局から、前記バッファ状態情報に対応するスケジューリング割当情報を受信し、該スケジューリング割当情報に基づき、優先順位の高いパケットデータを優先して出力するように前記優先順位キューを制御することを特徴とする請求項11に記載の装置。

【請求項16】

上りリンクパケットデータサービスを支援する移動通信システムにおいて、使用者端末が前記上りリンクパケットデータサービスのスケジューリング割当のためのスケジューリング情報を報告する装置であって、

同じ優先順位を持ち、少なくとも一つのサービスに関連するパケットデータを格納する複数の優先順位キューと、

前記逆方向パケットデータサービスのためにヘッダー部分とペイロード部分とから構成されたプロトコルデータユニットを生成し、前記優先順位キューから出力されたパケットデータを受信し、このパケットデータのヘッダー部分に前記スケジューリング情報を挿入し、前記ペイロード部分に前記パケットデータを挿入して送信するプロトコルデータユニット生成器と、

を含めてなることを特徴とする装置。

【請求項17】

前記スケジューリング情報は、

固有の優先順位を持ち、少なくとも一つのサービスに関連する複数の優先順位キューを表すキュー識別子と、前記優先順位キューに格納されているパケットデータの量を表すバッファペイロード情報とを含むことを特徴とする請求項16に記載の装置。

【請求項18】

前記バッファ状態情報は、

前記複数の優先順位キューのうち、格納されたデータが存在する少なくとも一つの優先順位キューを表すキュー識別子マップと、

前記キュー識別子マップが表す少なくとも一つの優先順位キューの識別子と、

前記キュー識別子マップが表す少なくとも一つの優先順位キューに格納されたデータの大きさと、

からなることを特徴とする請求項17に記載の装置。

【請求項19】

前記ヘッダー部分は、向上した逆方向専用伝送チャネル(EUDCH)のためのMAC(Media Access Control)シグナリングヘッダーであることを特徴とする請求項16に記載の装置。

【請求項20】

前記使用者端末にサービスを提供する基地局から、前記スケジューリング情報に対応するスケジューリング割当情報を受信し、該スケジューリング割当情報に基づき、優先順位の高いパケットデータを優先して出力するように前記優先順位キューを制御するスケジューリング制御器をさらに含むことを特徴とする請求項17に記載の装置。

【請求項21】

移動通信システムで使用者端末からの上りリンクパケットデータサービスをスケジューリングする基地局装置であって、

前記逆方向パケットデータサービスのために、ヘッダー部分とペイロード部分とから構成されたプロトコルデータユニットを受信する受信部と、

前記プロトコルデータユニットの前記ヘッダー部分から、前記上りリンクパケットデータサービスのためのスケジューリング情報を検出し、前記ペイロード部分からパケットデータを検出するヘッダー検出部と、

前記スケジューリング情報に基づいて前記上りリンクパケットデータサービスのためのスケジューリング割当情報を生成するスケジューラと、

前記スケジューリング割当情報を前記使用者端末に送信する送信部と、

を含めてなることを特徴とする装置。

【請求項22】

前記スケジューリング情報は、

固有の優先順位を持ち、少なくとも一つのサービスに関連する複数の優先順位キューを表すキュー識別子と、前記優先順位キューに格納されているパケットデータの量を表すバッファペイロード情報とを含むことを特徴とする請求項21に記載の装置。

【請求項23】

前記バッファペイロード情報は、

前記複数の優先順位キューのうち、格納されたデータが存在する少なくとも一つの優先順位キューを表すキュー識別子マップと、

前記キュー識別子マップが表す少なくとも一つの優先順位キューの識別子と、

前記キュー識別子マップが表す少なくとも一つの優先順位キューに格納されたデータの大きさと、

からなることを特徴とする請求項22に記載の装置。

【請求項24】

前記ヘッダー部分は、向上した逆方向専用伝送チャネル(EUDCH)のためのMAC(Media Access Control)シグナリングヘッダーであることを特徴とする請求項21に記載の装置。

【発明の詳細な説明】

【技術分野】

【0001】

本発明は、移动通信システムに関し、特に、上りリンク(Uplink: UL)を通してパケットデータを伝送するためのスケジューリング割当情報を効率よく送受信する方法及び装置に関する。

【背景技術】

【0002】

非同期方式である広帯域符号分割多重接続(Wideband Code Division Multiple Access: 以下、“WCDMA”と称する。)通信システムでは、上りリンクを通した高速のパケットデータサービスを支援するために、向上した逆方向専用チャネル(Enhanced Uplink Dedicated Channel: 以下、“EUDCH”と称する。)を使用する。このEUDCHは、非同期符号分割多重接続通信システムにおいて逆方向パケット伝送の性能を改善するために提案されたチャネルである。このようなEUDCH技術では、高速順方向パケット接続方式(High Speed Downlink Packet Access: 以下、“HSDPA”と称する。)で使用されているAMC(Adaptive Modulation and Coding)及びHARQ(Hybrid Automatic Retransmission Request)などの既存の方法の他に、より短い伝送時間区間(transmission time interval: 以下、“TTI”と称する。)を用いる新規の技術をも使用する。また、上りリンクチャネルには基地局(Node B)制御スケジューリングが適用される。この上りリンクに対するNode B制御スケジューリングは、下りリンクに対するスケジューリングと大きな違いを持つ。

【0003】

複数の使用者端末(User Equipment: 以下、“UE”と称する。)が送信した上りリンク信号は、相互間に直交性が保持されないため、これらの上りリンク信号は相互間に干渉信号として作用する。このため、Node Bが受信する上りリンク信号が増加するほど、特定UEが伝送する上りリンク信号に対する干渉信号の量も増加し、よって、Node Bの受信性能は低下してしまう。この種の問題は、上りリンク送信電力を増加させることで克服することができるが、この増加された送信電力を持つ上りリンク信号は、他の信号について干渉信号として作用する。したがって、前記Node Bは、下記の数学式1に示すように、前記受信性能を保証しつつ受信可能な上りリンク信号の量を制限する。

【0004】

〔数学式1〕

$$ROT = I_0 / N_0$$

【0005】

式中、 I_0 は、Node Bの全体受信広帯域電力スペクトル密度(Power spectral density)を表し、 N_0 は、Node Bの熱雑音電力スペクトル密度を表す。したがって、ROTは、Node BがEUDCHパケットデータサービスを受信するために割り当て得る上りリンク無線資源となる。

【0006】

図1 A及び図1 Bは、Node Bから割り当て得る上りリンク無線資源の変化を示している。図1 A及び図1 Bに示すように、Node Bが割り当て得る上りリンク無線資源は、ICI (Inter-cell interference)、音声トラヒック (Voice traffic)、及びEUDCHパケットトラヒックの和で表される。

【0007】

図1 Aは、Node B制御スケジューリングを使用しない場合の総ROT (Total ROT) の変化を示している。前記EUDCHパケットトラヒックに対してスケジューリングがなされないために、複数のUEが同時に高いデータレートで前記パケットデータを伝送すると、総ROTは目標ROT (Target ROT) よりも高くなり、上りリンク信号の受信性能の劣化につながる。

【0008】

図1 Bは、Node B制御スケジューリングを使用する場合の総ROTの変化を示している。Node B制御スケジューリングを使用すると、複数のUEが同時に高いデータレートで前記パケットデータを伝送するのを防止することができる。すなわち、このNode B制御スケジューリングは、特定のUEに高いデータレートを許容する場合にその他のUEには低いデータレートを許容することによって、総ROTが目標ROTを超えるのを防止する。したがって、このNode B制御スケジューリングによれば、常に一定の受信性能が保証される。

【0009】

Node Bは、前記EUDCHを使用するUEの要請データレートまたは上りリンクの送信品質を表すチャネル状況情報を用いて、各UE別にEUDCHデータ伝送可否を通報したり、それらのEUDCHデータレートを調整する。このNode B制御スケジューリングは、移動通信システムの性能を向上させるために、これらUEにデータレートを割り当て、Node Bの総ROTが目標ROTを越えないようにする。したがって、Node Bは、遠くにあるUEには相対的に低いデータレートを割り当て、近くにあるUEには相対的に高いデータレートを割り当てる。

【0010】

図2は、EUDCHに対するNode B制御スケジューリングの基本概念を示している。図2の200は、EUDCHを支援するNode Bを表し、210ないし216はEUDCHを使用するUEを表す。あるUEのデータレートが高くなると、Node BがこのUEからデータを受信する受信電力が増加し、よって、このUEのROTは、総ROTにおいて多い部分を占めることになる。一方、他のUEのデータレートが低くなると、Node Bがこの他のUEからデータを受信する受信電力が小さくなり、よって、この他のUEのROTは、総ROTにおいて少ない部分を占めることになる。前記Node Bは、データレートと無線資源間の関係、UEが要請するデータレートを考慮して前記EUDCHパケットデータに対するスケジューリングを遂行する。

【0011】

図2で、UE (210, 212, 214, 216) は、距離にしたがってNode B 200と相互に異なる逆方向送信電力でパケットデータを送信している。すなわち、Node B 200から最も遠く離れたUE 210は、最も高い逆方向チャネルの送信電力220でパケットデータを送信し、Node B 200と最も近くにあるUE 214は、最も低い逆方向チャネルの送信電力224でパケットデータを送信する。Node B 200は、総ROTを保持しながら他のセルに対するICIを減らし、かつ、移動通信シス

テムの性能を向上させるために、逆方向チャネルの送信電力の強さとデータレートが反比例するようにスケジューリングを遂行する。すなわち、逆方向チャネルの送信電力が最も高いUE 210に対しては相対的に小さいデータレートを割り当て、逆方向チャネルの送信電力が最も低いUE 214に対しては相対的に高いデータレートを割り当てる。

【0012】

図3は、EUDCHを伝送している端末302とこの端末302が属している基地局301間の基本的な送受信手順を示す流れ図である。

ステップS303で、基地局301と端末302間にEUDCHの設定(setup)がなされる。この記設定ステップは、専用伝送チャネル(Dedicated Transport Channel)を通じたメッセージの伝達ステップを含む。EUDCH設定が完了すると、ステップ304に示すように、端末302は、基地局301にスケジューリング情報を知らせる。該スケジューリング情報には、逆方向チャネル情報がわかるようにする端末送信電力情報、端末が送信しうる伝送電力余分値情報、及び端末のバッファに蓄えられている送信すべきデータの量が含まれる。

【0013】

続いて、基地局301は、ステップS311で、端末のスケジューリング情報をモニタリングしながら端末302をスケジューリングする。このステップ311で、基地局301が、端末302への逆方向データ伝送を許容すると決定した場合に、ステップS305で、基地局301は、端末302に割り当てられたデータレートと伝送タイミングなどを含むスケジューリング割当情報を伝送する。このスケジューリング割当情報に応答して、端末302は、ステップS312でEUDCH伝送のための伝送率などの伝送フォーマット(TF)を決定し、この伝送フォーマットを表す伝送フォーマットリソース指示子(Transport Format Resource Indicator: 以下、“TFRI”と称する。)を生成する。ステップS307で、端末302は、受信したスケジューリング割当情報を用いてEUDCHデータを伝送する。このEUDCHデータの伝送フォーマット(TF)を表す伝送フォーマットリソース指示子(TFRI)は、ステップS306で、EUDCHと同時に基地局301に伝送される。ステップS313で、基地局301は、受信したTFRIやEUDCHデータに誤りがあるか判断し、ステップS308で、基地局301は、このTFRI及びEUDCHデータ的一方にも誤りがある場合にはNACKを、両方にも誤りがある場合にはACKを、ACK/NACKチャネルを通して端末302に送る。

【0014】

基地局301は、スケジューリング情報に基づいて端末に割り当てるデータレートを定める。このときに、基地局は、EUDCHを使用する多数の端末に適宜のデータレートと伝送タイミングなどを割り当て、また、前記スケジューリングにおいて逆方向のROT値が目標ROT値を越えないように、各端末にリソースを割り当てる。このときに、システム全体の性能向上のために、チャネル状況の良好な端末に相対的に多くのリソースを割り当てることになる。

【0015】

図4は、上りリンクパケットデータサービスのために、端末が基地局に伝送するデータの類型を示している。

図4に示すように、端末400は、EUDCHを通して基地局402に対して、音声通話、パケットデータ、ゲームなどに関するデータを伝送することができる。このように端末が伝送するデータは、その類型によって異なるサービス品質(Quality of Service: QoS)を要求する。したがって、基地局が、端末が伝送しようとするデータに要求されるサービス品質に応じてスケジューリングを遂行し、無線資源を割り当てる方案が望まれている現状にある。

【発明の開示】

【発明が解決しようとする課題】

【0016】

したがって、上記の問題点に鑑みて、本発明の目的は、伝送するデータに要求されるサ

ービス品質に応じて無線資源を割り当てる方法及び装置を提供することにある。

【0017】

本発明の他の目的は、高いサービス品質を要請するデータに対しては多くの無線資源を割り当て、低いサービス品質を要請するデータに対しては低い無線資源を割り当てる方法及び装置を提供することにある。

【0018】

本発明のさらに他の目的は、サービス品質に応じて異なる無線資源を割り当てることによって、移動通信システムの無線資源を効率よく使用する方法及び装置を提供することにある。

【課題を解決するための手段】

【0019】

上記の目的を達成すべく、本発明の好ましい実施形態は、上りリンクパケットデータサービスを支援する移動通信システムにおいて、前記上りリンクパケットデータサービスのスケジューリング割当のために、使用者端末が伝送しようとするパケットデータを格納しているバッファのバッファ状態情報を報告する方法であって、固有の優先順位を持ち、少なくとも一つのサービスに関連する複数の優先順位キューに、該当する優先順位を持つパケットデータを格納するステップと、これらの優先順位キューのキュー識別子とこれらの優先順位キューに格納されているパケットデータの量を表すバッファペイロード情報とを含むバッファ状態情報を伝送するステップと、を含めてなることを特徴とする。

【0020】

本発明の他の実施形態は、上りリンクパケットデータサービスを支援する移動通信システムにおいて、使用者端末が前記上りリンクパケットデータサービスのスケジューリング割当のためのスケジューリング情報を報告する方法であって、前記逆方向パケットデータサービスのためにヘッダー部分とペイロード部分とから構成されたプロトコルデータユニットを生成するステップと、前記ヘッダー部分に前記スケジューリング情報を挿入し、前記ペイロード部分に、前記逆方向パケットデータサービスのためのパケットデータを挿入して伝送するステップと、を含むことを特徴とする。

【0021】

本発明のさらに他の実施形態は、上りリンクパケットデータサービスを支援する移動通信システムにおいて、前記上りリンクパケットデータサービスのスケジューリング割当のために、使用者端末が伝送しようとするパケットデータを格納しているバッファのバッファ状態情報を報告する装置であって、同じ優先順位を持ち、少なくとも一つのサービスに関連するパケットデータを格納する複数の優先順位キューと、これらの優先順位キューのキュー識別子と、これらの優先順位キューに格納されているパケットデータの量を表すバッファペイロード情報とを含むバッファ状態情報を生成するスケジューリング制御器と、前記バッファ状態情報を伝送する送信部と、を含めてなることを特徴とする。

【0022】

本発明のさらに他の実施形態は、上りリンクパケットデータサービスを支援する移動通信システムにおいて、使用者端末が前記上りリンクパケットデータサービスのスケジューリング割当のためのスケジューリング情報を報告する装置であって、同じ優先順位を持ち、少なくとも一つのサービスに関連するパケットデータを格納する複数の優先順位キューと、前記逆方向パケットデータサービスのためにヘッダー部分とペイロード部分とから構成されたプロトコルデータユニットを生成し、前記優先順位キューから出力されたパケットデータを受信し、このパケットデータのヘッダー部分に前記スケジューリング情報を挿入し、前記ペイロード部分に前記パケットデータを挿入して送信するプロトコルデータユニット生成器と、を含めてなることを特徴とする。

【0023】

本発明のさらに他の実施形態は、移動通信システムで使用者端末からの上りリンクパケットデータサービスをスケジューリングする基地局装置であって、前記逆方向パケットデータサービスのために、ヘッダー部分とペイロード部分とから構成されたプロトコルデー

タユニットを受信する受信部と、前記プロトコルデータユニットの前記ヘッダー部分から、前記上りリンクパケットデータサービスのためのスケジューリング情報を検出し、前記ペイロード部分からパケットデータを検出するヘッダー検出部と、前記スケジューリング情報に基づいて前記上りリンクパケットデータサービスのためのスケジューリング割当情報を生成するスケジューラと、前記スケジューリング割当情報を前記使用者端末に送信する送信部と、を含めてなることを特徴とする。

【発明の効果】

【0024】

本発明は、端末から、向上した上りリンクチャネルを通して要求される優先順位の異なるデータを同時に伝送するときに、このデータの優先順位を基地局制御スケジューリングで反映する。このために、端末がサービス品質に対応する優先順位キューのバッファ状態情報を伝達し、基地局は伝えられた優先順位キューのバッファ状態情報を用いてスケジューリングを遂行する。したがって、本発明によれば、要求される優先順位に対応する差別化したサービスを提供することができ、使用者の要求を充足させることが可能になる。

【発明を実施するための最良の形態】

【0025】

以下、本発明の好ましい実施形態について、添付図面を参照しつつ詳細に説明する。なお、本発明を説明するにあたり、関連する公知機能や構成についての具体的な説明が本発明の要旨を曖昧にするのを避けるために、その詳細な説明は省略する。

【0026】

第3世代移動通信の一つであるUMTS(Universal Mobile Telecommunication Service)システムは、GSM(Global System for Mobile communication)とGPRS(General Packet Radio Services)通信標準に基盤を置いているが、TDMA(Time Division Multiple Access)を使用するGSMとは違い、広帯域(Wideband)CDMA技術を使用する。UMTSシステムの無線接続ネットワーク(UMTS Terrestrial Radio Access Network: 以下、“UTRAN”と称する。)は、複数のセルを含む基地局とこれらの基地局の無線資源を管理する無線ネットワーク制御器(Radio Network Controller: 以下、“RNC”と称する。)を含めて構成される。

【0027】

端末とRNC間のインターフェースは、Uuインターフェースと称し、制御及びシグナリング信号を交換するための制御平面(Control Plane)と、データトラヒックを伝送するための使用者平面(User Plane)とに区分される。前記制御平面にはRRC(Radio Resource Control)階層、RLC(Radio Link Control)階層、MAC(Media Access Control)階層、及び物理(Physical: 以下、“PHY”と称する。)階層が存在し、使用者平面には、PDCP(Packet Data Control Protocol)階層、RLC階層、MAC階層、及び物理階層が存在する。ここで、物理階層は各セルに位置し、MAC階層からRRC階層までは、RNCに位置する。

【0028】

特に、MAC階層において、使用者平面と関連する部分は、MAC-dと呼ばれ、制御平面に関連する部分は、MAC-cと呼ばれる。専用伝送チャネルを通して伝送しようとする使用者データは、MAC-d階層を通して所望の大きさの伝送ブロックに生成される。使用者データをEUDCHを通して伝送しようとする場合、伝送ブロックはMAC階層でMAC-eu部分を経ることになる。MAC-eu階層は、MAC-d階層から送られてきたデータを物理階層に伝達するに先立って、EUDCHのための基地局制御スケジューリング、HARQなどの処理を担う。

【0029】

図5は、本発明の好ましい実施形態によって、EUDCHを伝送する端末のMAC-eu階層構造を示す図である。

端末のMAC-eu階層500は、順位分配器(Priority Queue distributor)502と

、優先順位キュー(Priority Queue: PQ) 504とを含む。このMAC-e u階層500は、MAC-d階層518から基地局に伝送するデータを受信する。この受信データは、MAC-e u階層500の順位分配器502に伝えられるし、この順位分配器502は、受信したデータに対する優先順位を決定した後に、その優先順位に対応する優先順位キュー504にバッファリングする。

【0030】

これらの優先順位キュー504は、提供しようとするサービスの優先順位にしたがってデータを格納するのに使用され、それぞれ固有のキュー識別子(Queue Identifier)を持つ。すなわち、これらの優先順位キュー504はそれぞれ、少なくとも一つのサービスにそれぞれ関連され、相互に異なる優先順位を持つデータを格納する。図5では二つの優先順位キュー504が示されているが、提供しているサービスの種類と個数に対応するMAC制御信号516に応じて、優先順位キュー504の個数は任意に決定される。すなわち、基地局に伝達するデータに対する優先順位を多段階に構成しようとする場合には、これら優先順位キュー504の個数は増加する。この優先順位は、データを基地局に伝送する伝送時点、すなわち要求される遅延によって決定される。つまり、基地局に早い時間内に伝送すべきデータは、優先順位が高く、基地局に早い時間内に伝送しなくてもいいデータは、優先順位が低い。

【0031】

順位分配器502は、受信したデータに対する優先順位を決定し、この決定された優先順位に対応する優先順位キュー504にそのデータを伝達する。これにより、同じ優先順位を持つデータは、同一の優先順位キューに伝えられる。これらの優先順位キュー504は、基地局からスケジューリングによりリソースが割り当てられるまで、受信データを格納する。

【0032】

MAC-e u階層500は、基地局にスケジューリング割当を要請するために、これらの優先順位キュー504に格納されたデータの量を表すバッファ状態情報と、上りリンクの送信品質を表すチャネル状態情報を含むスケジューリング情報とを、EUDCH関連上りリンク510を通して伝送する。基地局が、EUDCH関連下りリンク514を通して端末にスケジューリング割当情報を伝送すると、このスケジューリング割当情報を用いてTFC(TF Combination)選択部508はTFCを決定し、この決定されたTFCを用いて、優先順位キュー504からデータを読み出してEUDCH(512)を通して伝送する。この場合に、端末は、優先順位の高い優先順位キュー504に格納されているデータをまず伝送する。こうすると、優先順位に応じて伝送時間を異なつて指定することが可能になる。一方、HARQ個体506は、受信したデータに対して、関連下りリンク514を通して受信されるACK/NACKを解析し、ACKが受信される場合には該当の優先順位キューに格納されたデータを廃棄し、NACKが受信される場合には当該の優先順位キューに格納されたデータを再伝送する。

【0033】

図6は、本発明の一実施形態によって二つの端末が一つの基地局にスケジューリング割当を要請する動作に示している。

図6において、端末1(610)は、二つの優先順位キュー612、614を含み、端末2(620)は、一つの優先順位キュー622を含んでいる。端末1(610)の優先順位キュー1(612)は、優先順位キュー2(614)に比べて高い優先順位を持ち、端末2(620)の優先順位キュー1(622)は、端末1(610)の優先順位キュー1(612)と同じ優先順位を持つ。端末1(610)の優先順位キュー1(612)は、100ビットのデータを格納しており、端末1(610)の優先順位キュー2(614)は、300ビットのデータを格納している。また、端末2(620)の優先順位キュー1(622)は、300ビットのデータを格納している。この基地局(600)は、450ビットだけのデータを受信しようとする無線資源を持つ。

【0034】

図6を参照すると、端末610、620は、基地局600に伝送するデータの量を表すバッファ状態情報630、632を伝送する。すなわち、端末1(610)は、400ビットに対応するバッファ状態情報630を基地局600に伝送し、端末2(620)は、300ビットに対応するバッファ状態情報632を基地局600に伝送する。この場合に、これらの端末610、620の上りリンクチャネル状況が同一であると、基地局600は、端末1(610)に対しては、200ビットだけを伝送することを許容するスケジューリング割当情報(640)を伝送し、端末2(620)に対しては、150ビットだけを伝送することを許容するスケジューリング割当情報(642)を伝送する。

【0035】

端末1(610)は、スケジューリング割当情報640を用いてTFCを決定し、この決定されたTFCを用いてEUDCHを通してデータを伝送する。すなわち、優先順位にしたがって、まず、優先順位キュー1(612)に待機している100ビットのデータが伝送され、優先順位キュー2(614)に待機している100ビットのデータが伝送される。端末2(620)もまた、スケジューリング割当情報(642)を用いてTFCを決定し、この決定されたTFCを用いてEUDCHを通してデータを伝送する。すなわち、優先順位キュー1(622)に待機している150ビットのデータが伝送される。

【0036】

この場合に、端末2(620)の優先順位キュー1(622)は、端末1の優先順位キュー2(614)よりも高い優先順位を持つにもかかわらず、その待機している全てのデータを伝送することができない。すなわち、基地局(600)に対してスケジューリング割当情報を要請する端末が一つである場合には、優先順位にしたがって待機しているデータを伝送すればいいが、基地局に対してスケジューリング割当情報を要請する端末が少なくとも二つである場合には、相対的に高い優先順位を持つデータが、後で伝送される、という問題点が生じる。

【0037】

そこで、図7では、図6の問題点を解決するための本発明の好ましい実施形態を提示している。図7で、端末710、720は、データの量のみならず、優先順位に関する情報も同時に基地局700に伝送する。

【0038】

図7を参照すると、端末1(710)は、二つの優先順位キュー712、714を含み、端末2(720)は、一つの優先順位キュー722を含んでいる。端末1(710)の優先順位キュー1(712)は、優先順位キュー2(714)に比べて高い優先順位を持ち、端末2(720)の優先順位キュー1(722)は、端末1(710)の優先順位キュー1(712)と同じ優先順位を持つ。端末1(710)の優先順位キュー1(712)は、100ビットのデータを格納しており、端末1(710)の優先順位キュー2(714)は、300ビットのデータを格納している。また、端末2(720)の優先順位キュー1(722)は、300ビットのデータを格納している。

【0039】

端末710、720は、基地局(700)に伝送するデータの量と優先順位に関する情報とを含むバッファ状態情報730、732を伝送する。すなわち、端末1(710)は、400ビットに対応するデータ量と優先順位を表すキュー識別子(Queue Identification: QID)とを含むバッファ状態情報730を、基地局700に伝送する。このバッファ状態情報730は、優先順位1に対応するデータ量が100ビットであり、優先順位2に対応するデータ量が300ビットであることを表す。端末2(720)は、300ビットに対応するデータ量と優先順位を表すQIDとを含むバッファ状態情報732を、基地局700に伝送する。これらの端末710、720に対する上りリンクチャネル状況が同一であれば、基地局700は、優先順位を考慮して端末710、720にスケジューリング割当情報740、742を伝送する。このときに、基地局700は、端末1(710)に対しては、100ビットだけを伝送することを許容するスケジューリング割当情報740を伝送し、端末2(720)に対しては、250ビットだけを伝送することを許容するスケ

ジューリング割当情報742を伝送する。

【0040】

端末1(710)は、スケジューリング割当情報740を用いてTFCを決定し、この決定されたTFCを用いてEUDCHを通してデータを伝送する。すなわち、優先順位にしたがって、優先順位キュー1(712)に待機している100ビットのデータが伝送される。端末2(720)もまた、スケジューリング割当情報(742)を用いてTFCを決定し、この決定されたTFCを用いてEUDCHを通してデータを伝送する。すなわち、優先順位キュー1(722)に待機している250ビットのデータが伝送される。このように端末1(710)と端末2(720)は、優先順位が高いデータを先に伝送する。

【0041】

図8は、本発明の好ましい実施形態に従う端末のMAC-euスケジューリング制御器の構造を示す図である。

図8を参照すれば、スケジューリング制御器(Scheduling Controller)800は、環境制御器(Configuration Controller)804、優先順位キュー制御器(PQ Controller)802、及びTFC選択部806で構成されている。優先順位キュー制御器802は、優先順位キュー(図示せず)からバッファペイロード情報810、812を受ける。このバッファペイロード情報810、812は、各優先順位キューに待機しているデータの量を意味する。図8では、n個の優先順位キューがあると仮定している。参照番号810は、優先順位キュー1から送られてくるバッファペイロード情報であり、参照番号812は、優先順位キューnから送られてくるバッファペイロード情報である。また、優先順位キュー制御器802は、環境制御器804からキュー情報814が入力される。このキュー情報814は、優先順位キューの設定情報(configuration information)であって、優先順位キューのメモリの大きさと個数に関連する。優先順位キュー制御器802は、バッファペイロード情報810、812と該当のバッファペイロード情報の優先順位に関するQIDを含むバッファ状態情報826とを、EUDCH送信部828を介して基地局に伝送する。

【0042】

TFC選択部806は、E-SCCH(Shared Control Channel for EUDCH)(図示せず)を通してスケジューリング割当情報820が入力される。また、このTFC選択部806は、優先順位キュー制御器802から優先順位キューに対するバッファ状態情報816入力され、環境制御器804からスケジューリング環境(configuration)情報が入力される。このスケジューリング環境情報には、優先順位キューの優先順位やTFCs(Transport Format Combination Set)などが含まれる。TFC選択部806は、バッファ状態情報816とスケジューリング割当情報820を用いてTFCを決定する。TFCは、優先順位の高い優先順位キューに格納されているデータを先に伝送するように決定される。

【0043】

この決定されたTFCを、TFC選択部806は、E-DPDCH(Dedicated Physical Data Channel for EUDCH)送信部824に伝達する。E-DPDCH送信部824は、この受信したTFCを用いてEUDCHパケットデータを伝送する。前記決定されたTFCは、E-DPCCCH(Dedicated Physical Control Channel for EUDCH)送信部822に伝えられる。E-DPCCCH送信部822は、TFCを含む制御情報を、EUDCHパケットデータと同一の時点で伝送する。また、このTFCは、優先順位キュー制御器802に伝えられる。優先順位キュー制御器802は、受信したTFCを用いて、どの優先順位キューに待機しているデータが伝送されたか把握し、優先順位キューのバッファ状態を更新する。

【0044】

図9は、本発明の好ましい実施形態に従うMAC-euスケジューリング制御器の動作を示すフローチャートである。

図9を参照すると、ステップS900で、スケジューリング制御器は、優先順位キューから入力されるバッファペイロード情報に基づいて、優先順位キューに新規のデータが

到達したか否かを判断する。このスケジューリング制御器は、どの優先順位キューからバッファペイロード情報が入力されたかを判断することによって、優先順位キューに伝送されたデータの量と優先順位が分かる。これらの優先順位キューに新規のデータが到達された場合にはステップS902に移行し、優先順位キューに新規のデータが到達しなかった場合には、ステップS900に戻る。

【0045】

ステップS902で、スケジューリング制御器は、バッファペイロード情報とバッファペイロード情報に関連した優先順位を表すキュー識別子を含むバッファ状態情報を、基地局に伝送する。

【0046】

ステップS904で、スケジューリング制御器は、基地局からスケジューリング割当情報が受信されるか否かを判断する。このスケジューリング割当情報には、端末が使用可能な最大データレートと許容タイミングに関する情報が含まれる。基地局からスケジューリング割当情報が受信された場合には、ステップS906に移行し、スケジューリング割当情報が受信されなかった場合には、ステップS904に復帰する。

【0047】

ステップS906で、スケジューリング制御器は、スケジューリング割当情報により割り当てられたデータレート内でTFCを決定する。このTFCを決定するにおいて、優先順位キューに伝送されたデータの優先順位を考慮し、高い優先順位を持つデータが先に伝送されるようにする。ステップS908で、スケジューリング制御器は、決定されたTFCを用いて、優先順位キューに伝送されたデータを伝送するように制御する。この制御命令に応じてMAC-eu階層は、該当の優先順位キューから読み出したデータを含むMAC-eu PDU(Protocol Data Unit)を生成し、この生成されたMAC-eu PDUを、E-DPDCHを通して伝送する。図9には図示せぬが、スケジューリング制御器は、決定されたTFCをE-DPDCHを通して伝送し、変更されたバッファ状態情報に関する情報を更新する。この更新されたバッファ状態情報は、EUDCHを通して伝送される。

【0048】

図10は、本発明の好ましい実施形態に従う、端末と基地局間のMAC-euシグナリングを示す図である。図10に示すように、端末のMAC-eu階層1000は、基地局のMAC-eu階層1002にバッファ状態情報を伝送している。このバッファ状態情報は、上にも述べたように、キュー識別子と優先順位キューのバッファペイロードを含む。

【0049】

図11は、本発明の好ましい実施形態によってバッファ状態情報を含むMAC-eu PDUの構成を示す図である。図11に示すように、MAC-eu PDUは、ヘッダ部分に受納されるMAC-euヘッダ1100と、ペイロード部分に受納される複数個のMAC-eu SDU(Service Data Unit)1102とから構成される。MAC-euヘッダ1100に含まれる情報は、下記の通りである。

【0050】

バージョンフラグ(Version Flag:VF)は、MAC-eu PDUフォーマットのバージョンを表す。

キュー識別子(QID)は、MAC-eu SDUが出力された優先順位キューの識別子であって、3ビットで構成される。

伝送シーケンス番号(Transmission Sequence Number:TSN)は、優先順位にしたがってMAC-eu SDUを再整列するための一連番号であって、5ビット乃至6ビットで構成される。

SID_kは、MAC-eu PDUを構成するMAC-eu SDUの集合のうち、x番目のMAC-eu SDU集合に属するMAC-d SDUの大きさを表し、2ビット乃至3ビットで構成される。

N_kは、x番目のMAC-e u SDU集合に属するMAC-d PDUの個数を表し、7ビットで構成される。

F (Flag)は、1に設定されると、続くフィールドがMAC-e u PDUであることを表し、Fが0に設定されると、続くフィールドがSIDであることを表す。

キュー識別子マップ(QID map)は、データが存在する優先順位キューの識別子を表すマップであって、優先順位キューの個数だけのビット数が割り当てられる。1は、データが存在することを表し、0は、データが存在しないことを表す。バッファペイロード(buffer payload)は、キュー識別子マップの値が1の優先順位キューに格納されたデータの大きさを表し、キュー識別子マップの長さによるビット数が割り当てられる。

【0051】

図12は、本発明の好ましい実施形態に従う基地局のMAC-e uスケジューラの構造を示す図である。

図12を参照すると、スケジューラ1200は、端末状態分析器(UE status Analyzedr)1202とリソース制御器1204とから構成される。端末状態分析器1202は、基地局が管理するセル領域にある端末UE#1, UE#2, UE#Nのバッファ状態情報とチャネル状態情報1210, 1212, 1214を受信する。端末状態分析器1202は、各端末が伝送したMAC-e u PDUのMAC-e uヘッダーに含まれている優先順位キューに従うバッファ状態情報を受け、これに基づいて各端末の優先順位キューに格納されたデータの量を推定する。端末状態分析器1202は、各端末に対するデータ量推定値をリソース制御器1204に伝達する。

【0052】

リソース制御器1204は、各端末に対するデータ量推定値、チャネル状態情報、及び無線網制御器からNBAP(Node B Application Protocol)を通じて提供されたターゲットROTを考慮して、特定端末に割り当てるROTを計算し、端末の優先順位キューの優先順位を考慮して、この端末に割り当てる最大許容データレートを決定する。TFCが決定されると、端末から伝送可能なデータの大きさと伝送電力のオフセットが前記TFCによって決定される。各端末に割り当てる最大許容データレートは、最大許容TFC情報1220, 1222に含まれ、E-SCCH送信部1224, 1226を介して端末に伝送される。

【0053】

図13は、本発明の好ましい実施形態に従う基地局のMAC-e uスケジューラの動作を示すフローチャートである。

図13を参照すると、ステップS1300で、スケジューラは、端末からスケジューリング情報を含むMAC-e u PDUが受信されたか否かを判断する。このスケジューリング情報は、各端末のバッファペイロード情報と各バッファの優先順位に関する情報とを含む。この判断結果、スケジューリング情報が受信された場合には、ステップS1302に移行し、スケジューリング情報が受信されなかった場合にステップS1300に復帰する。

【0054】

ステップS1302で、スケジューラは、端末から受信したバッファ状態情報とチャネル情報に基づいて、この端末に割り当てる最大許容データレートを決定する。この最大許容データレートは、無線網制御器から提供されたターゲットROT及び端末が伝送するデータの優先順位を考慮して決定する。この最大許容データレートは、ステップS1304段階でEUDCHに関連した制御チャネルを通して端末に伝送される。

【0055】

図14は、本発明の好ましい実施形態に従う端末の送受信動作の構造を示す図である。まず、スケジューリング割当情報を受信する受信側における動作について述べる。

図14を参照すると、アンテナから入力された受信信号は、RF(Radio Frequency)部(RF Unit)1442を経て基底帯域信号に変換された後に、デスクランブラ1400に入力される。デスクランブラ1400は、受信した基底帯域信号を、スクランプリングコード

$S_{d1,n}$ を使ってディスクランプリングする。ディスクランプリングされた信号は、逆拡散器1402に送られる。このディスクランプリングされた信号をチャネル区分(channelization)するために、逆拡散器1402は、このディスクランプリングされた信号にチャネルコード(Channelization Code) C_{es} を乗じ、チャネル区分された信号を復調部1404に伝達する。チャネル区分された信号は、復調部1404で復調された後に、デコーディング部1406でデコーディングされる。E-SCCH検出部1408は、デコーディングされた信号からスケジューリング割当情報を検出する。このスケジューリング割当情報は、端末に割り当てられた最大許容TFC情報1410を含む。

【0056】

最大許容TFC情報1410は、MAC-euスケジューリング制御器1412に伝えられる。MAC-euスケジューリング制御器1412は、最大許容TFC情報1410を用いてTFCを決定する。このTFCは、優先順位キュー1422, 1424に待機しているデータの優先順位に関する情報を考慮して決定する。このために、優先順位キュー1422, 1424は、相互に異なる優先順位を持つ少なくとも一つのサービスに関連したデータを格納し、新規のデータが到達する度にまたは周期的にキュー識別子とバッファークペイロード情報をMAC-euスケジューラ制御器1412に伝達する。MAC-euスケジューラ制御器1412は、前記決定されたTFCに関する情報を、E-DPCH生成器1414に伝達する。E-DPCH生成器1414は、他の制御情報とTFCとを含む制御信号を生成する。この生成された制御信号は、コーディング部1416でコーディングされた後に、変調部1418で変調され、チャネルコード C_{ec} を用いて拡散器1420でチャネル区分(channelization)された後に、多重化器1438に伝えられる。

【0057】

MAC-eu PDU生成器1428は、2つの機能を遂行する。その一つは、前記MAC-euスケジューリング制御器1412から伝達されたキュー識別子とバッファーク状態情報を、MAC-euヘッダーに含ませる。また、スケジューリング制御器1412から伝達されたTFCを用いて、優先順位キュー1422, 1424に待機しているデータにMAC-euヘッダーを添付することで、MAC-eu PDUを生成する。このMAC-eu PDUは、コーディング部1430でコーディングされ、レートマッチング部1432でレートマッチングされる。このレートマッチングされた信号は、変調部1434で変調され、拡散器1436でチャネルコード C_c によりチャネル区分(Channelization)される。このチャネルコーディングされたデータは、多重化器1438に伝えられる。この多重化器1438は、拡散器1420, 1436から伝達された信号と他のチャネルの信号を多重化する。これら多重化された信号は、スクランブラー1440によりスクランプリングコード $S_{dpcch,n}$ によりスクランプリングされた後に、RF部1444でRF信号に変換され、アンテナから基地局へ伝送される。

【0058】

図15は、本発明の好ましい実施形態に従う基地局の送受信動作の構造を示す図である。まず、スケジューリング情報を受信する受信側における動作について述べる。基地局の受信部は、上りリンクパケットデータサービスを遂行するN個の端末それぞれに対応するN個の受信経路1540, 1542を持つ。ここでは、UE#1に対応する受信経路1540の動作について説明するが、残りの受信経路も同様の動作を遂行することは言うまでもない。

【0059】

アンテナから伝えられた受信信号は、RF部1538を経て基底帯域信号に変換された後に、デスクランブラ1518に入力される。デスクランブラ1518は、基底帯域信号をスクランプリングコード $S_{dpcch,n}$ によりディスクランプリングする。このディスクランプリングされた信号は、逆拡散器1520, 1522に伝えられてE-DPCH信号とE-DPDCH信号とにチャネル区分される。逆拡散器1522でチャネルコード C_{ec} によりチャネル区分されたE-DPCH信号は、復調部1524で復調された後に、デコーディング部1526でデコーディングされる。続いて、制御情報検出部1527は、デ

コーディング部1526でデコーディングされたデータから、EUDCHデータを受信する上で必要な制御情報を検出する。この制御情報は、EUDCHデータの変調情報などを含む。

【0060】

逆拡散器1520でチャネルコード C_{cs} により逆拡散されたE-DPDCHは、復調部1528で、制御情報検出部1527で検出された変調情報により復調され、レートデマッチング部1530によりデマッチングされた後に、デコーディング部1532でデコーディングされる。

【0061】

MAC-euヘッダー検出部1534は、デコーディング部1532から伝えられたMAC-eu PDUでヘッダー内のバッファ状態情報とペイロード内のデータを分割する。MAC-euヘッダー検出部1534は、MAC-euヘッダー内のキュー識別子マップ(QID map)が0でない値を持っていれば、MAC-euヘッダーに含まれているバッファ状態情報1516を検出してMAC-euスケジューラ1514に伝達する。このバッファ状態情報1516は、少なくとも一つのキュー識別子とバッファペイロード情報とから構成される。また、MAC-euヘッダー検出部1534は、MAC-euヘッダー以外の部分であるMAC-eu SDUを分離し、これらを上位階層の再整列バッファ(Reordering Buffer) (図示せず)に伝達する。これらの再整列バッファは、RNC内に位置し、かつ、端末側の優先順位キューと対応して、受信されるMAC-eu SDUをそれらの伝送シーケンス番号(TSN)にしたがって整列する。

【0062】

MAC-euスケジューラ1514は、バッファ状態情報1516と他のスケジューリング情報を用いて、各端末のための最大許容TFC情報1512を生成し、この最大許容TFC情報1512をE-SCCH生成器1510に伝達する。この最大許容TFCは、バッファ状態情報に含まれている、伝送するデータに対する優先順位を考慮して決定される。E-SCCH生成器1510は、前記最大許容TFC情報に対するスケジューリング割当情報を生成する。このスケジューリング割当情報は、コーディング部1508によりコーディングされ、変調部1506により変調される。変調部1506により変調された信号は、拡散器1504でチャネルコード C_{cs} によりチャネル区分された後に、多重化器1502に伝えられる。このチャネル区分された信号は、多重化器1502で他の下りリンクチャネル信号と多重化される。この多重化された信号は、スクランブラー1500でスクランプリングコード $S_{d1,n}$ によりスクランプリングされた後に、RF部1536によりRF信号に変換された後に、アンテナから端末に伝送される。

【0063】

一方、本発明の詳細な説明では具体例について説明してきたが、本発明の範囲を逸脱しない限度内で各種の変形が可能であることは勿論である。したがって、本発明の範囲は、上述の具体例に限定されてはいけなく、特許請求の範囲及びこの範囲と均等なものにより定められるべきである。

METHOD AND APPARATUS FOR SCHEDULING ASSIGNMENT OF
UPLINK PACKET TRANSMISSION IN MOBILE
TELECOMMUNICATION SYSTEM

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a mobile telecommunication system, and more particularly to a method and an apparatus for efficiently transceiving scheduling assignment information for transmitting packet data through an uplink (UL).

2. Description of the Related Art

An asynchronous Wideband Code Division Multiple Access (hereinafter, referred to as a WCDMA) communication system employs an Enhanced Uplink Dedicated Channel (hereinafter, referred to as an EUDCH or E-DCH) in order to support a high speed packet data service through an uplink. The EUDCH is a channel proposed to improve the performance of a packet transmission in an uplink communication in an asynchronous code division multiple access communication system. The EUDCH-related technology includes new technologies for a more reduced Transmission Time Interval (TTI) together with the Adaptive Modulation and Coding (AMC) method and the Hybrid Automatic Retransmission Request (HARQ) method already used in a High Speed Downlink packet access (HSDPA). Further, a Node B control scheduling of an uplink channel is used. The Node B control scheduling for the uplink is very different from a scheduling for a downlink.

Since uplink signals transmitted from a plurality of user equipments (hereinafter, referred to as UEs) do not maintain orthogonality between the

uplink signals, the uplink signals function as interference signals between themselves. Therefore, as the number of uplink signals received in the Node B increase, the number of interference signals for uplink signals transmitted from a specific UE also increases. Accordingly, as the number of the interference signals with respect to the uplink signals transmitted from the specific UE increases, the reception performance of the Node B is reduced. In order to overcome such a problem, uplink transmission power may be increased. However, an uplink signal having increased transmission power also functions as an interference signal with respect to another signal. Accordingly, the Node B limits the number of a receivable uplink signals while ensuring its own reception performance. Equation (1) represents the number of the receivable uplink signal while the reception performance of the Node B is ensured.

$$ROT = \frac{I_o}{N_o} \quad \dots \dots (1)$$

In Equation (1), I_o represents an entire reception wideband power spectral density of the Node B and N_o represents a thermal noise power spectral density of the Node B. Accordingly, the ROT is a radio resource capable of being assigned by the Node B for the EUDCH packet data service in an uplink.

FIGs. 1A and 1B show variations of an uplink radio resource assigned by a Node B. As shown in FIGs. 1A and 1B, the uplink radio resource assigned by the Node B is obtained by the sum of inter-cell interference (hereinafter, referred to as an ICI), voice traffic, and EUDCH packet traffic.

FIG. 1A shows variation of the total ROT when Node B scheduling is not used. Since scheduling is not performed for the EUDCH packet traffic, the total ROT grows larger than a target ROT when a plurality of UEs transmit the packet data at a high data rate at the same time. Herein, the reception performance of the uplink signal is reduced.

FIG. 1B shows variation of the total ROT when Node B scheduling is used, thereby preventing the multiple UEs from transmitting the packet data at a

high data rate at the same time. That is, the Node B scheduling enables a high data rate to be permitted to a specific UE and a low data rate to be permitted to other UEs, thereby preventing the total ROT from exceeding the target ROT. Accordingly, Node B scheduling can always maintain constant reception performance.

The Node B notifies each UE of information regarding whether or not EUDCH data can be transmitted by means of a request data rate of UEs using the EUDCH or channel status information representing transmission quality of an uplink. Also, the Node B adjusts the EUDCH data rate. Further, in order to improve the performance of a mobile communication system, the Node B scheduling assigns the data rate to the UEs so that the total ROT of the Node B does not exceed the target ROT. For example, the Node B may assign a low data rate to a UE in a position remote from the Node B and a high data rate to a UE in a position near to the Node B.

FIG. 2 is a view illustrating a basic concept regarding circumstances in which a Node B scheduling is used in an EUDCH. In FIG. 2, Node B 200 supports the EUDCH and reference numerals 210, 212, 214, and 216 represent UEs transmitting the EUDCH. When a data rate of a certain UE increases, reception power received in the Node B 200 from the UE increases. Accordingly, a ROT of the UE occupies a large portion of the total ROT. In contrast, when a data rate of another UE is reduced, reception power received in the Node B 200 from another UE is reduced. Accordingly, a ROT of another UE occupies a small portion of the total ROT. The Node B 200 performs the Node B scheduling for the EUDCH packet data in consideration of the relation between the data rates and a radio resource requested by the UEs 210, 212, 214, and 216.

In FIG. 2, the UEs 210, 212, 214, and 216 transmit the packet data with different uplink transmission powers from each other according to the distance between the Node B 200 and the UEs 210, 212, 214, and 216. UE 210, in the furthest position from the Node B 200, transmits the packet data with the highest

transmission power 220 of an uplink channel. In contrast, UE 214, in the nearest position to the Node B 200, transmits the packet data with the lowest transmission power 224 of an uplink channel. In order to improve the performance of a mobile communication system while maintaining the total ROT and reducing an ICI for another cell, the Node B performs scheduling so that the transmission power intensity of the uplink channel is inversely proportional to the data rate, thereby assigning a relatively lower data rate to the UE 210 having the highest transmission power of an uplink channel and a relatively higher data rate to the UE 214 having the lowest transmission power of an uplink channel.

FIG. 3 is a flow diagram illustrating a basic transmission/reception procedure between a UE 302 transmitting an EUDCH and a Node B 301 including the UE 302.

In step 303, a setup of an EUDCH is accomplished between the Node B 301 and the UE 302. The setup step includes a transmission step of messages through a dedicated transport channel. When the EUDCH setup is accomplished, the UE 302 informs the Node B 301 of scheduling information at step 304. The scheduling information may include UE transmission power information enabling uplink channel information to be understood, extra information of transmission power capable of being transmitted by a UE, and the amount of data stored in a buffer of a UE that must be transmitted.

In step 311, the Node B 301 monitors the scheduling information of the UE 302 and schedules the UE 302. When the Node B 301 determines to permit an uplink data transmission to the UE 302 in step 311, the Node B 301 transmits scheduling assignment information containing an assigned data rate and a transmission timing to the UE 302 in step 305. In step 312, the UE 302 determines a Transport Format (TF) such as a data rate for a EUDCH transmission based on the scheduling assignment information and chooses a Transport Format Resource Indicator (TFRI) indicating the TF. In step 307, the UE 302 transmits EUDCH data by means of the TFRI. Further, the TFRI, which is related information representing the TF of the EUDCH data, is

transmitted to the Node B 301 in step 306 together with the EUDCH data. In step 313, the Node B 301 determines whether or not an error exists in the TFRI and the EUDCH data. As a result of the determination, when the error exists in at least one of the TFRI and the EUDCH data, the Node B 301 transmits an NACK to the UE 302 through an ACK/NACK channel, in step 308. In contrast, when any error does not exist in the TFRI and the EUDCH data, the Node B 301 transmits an ACK to the UE 302 through an ACK/NACK channel, in step 308.

The Node B 301 decides a data rate to be assigned to a UE on the basis of the scheduling information. Herein, the Node B 301 assigns a proper data rate and transmission timing to multiple UEs using an EUDCH. Further, in the scheduling, the Node B 301 assigns a resource to each UE in order to prevent a ROT value of an uplink from exceeding a target ROT value. Herein, the Node B 301 assigns many resources to a UE having a good channel condition in order to improve the entire performance of a system.

FIG. 4 is a view showing the types of data transmitted from a UE to a Node B for an uplink packet data service.

As shown in FIG. 4, a UE 400 can transmit voice and image traffic, packet data, data regarding a game, etc., to a Node B 402 through an EUDCH. The data transmitted from the UE as described above requires different quality of service (QoS) according to the types of the data. Accordingly, it is necessary to provide a method by which the Node B 402 performs a scheduling and assigns a radio resource according to quality of service required by data to be transmitted from a UE.

SUMMARY OF THE INVENTION

Accordingly, the present invention has been made to solve the above-mentioned problems occurring in the prior art, and it is an object of the present invention is to provide a method and an apparatus for assigning a radio resource according to quality of service required by data to be transmitted.

It is another object of the present invention is to provide a method and an apparatus for assigning many radio resources with respect to data requesting high quality of service and a few radio resources with respect to data requesting low quality of service.

It is further object of the present invention is to provide a method and an apparatus for efficiently using a radio resource of a mobile communication system by assigning radio resources different from each other according to quality of service.

In order to accomplish the aforementioned objects, according to one aspect of the present invention, there is provided a method for reporting status of a buffer storing packet data to be transmitted by a user equipment for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the method including storing packet data having a priority corresponding to a plurality of priority queues having inherent priorities and relating to at least one service; and transmitting buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues.

In order to accomplish the aforementioned objects, according to another aspect of the present invention, there is provided a method which enables a user equipment to report scheduling information for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the method including generating a protocol data unit including a header part and a payload part for the uplink packet data service; and inserting the scheduling information into the header part, inserting packet data for the uplink packet data service into the payload part, and transmitting the protocol data unit.

In order to accomplish the aforementioned objects, according to a further aspect of the present invention, there is provided an apparatus for reporting status of a buffer storing packet data to be transmitted by a user equipment for a

scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the apparatus including a plurality of priority queues having same priorities, for storing packet data relating to at least one service; a scheduling controller for generating buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues; and a transmission unit for transmitting the buffer status information.

In order to accomplish the aforementioned objects, according to still another aspect of the present invention, there is provided an apparatus which enables a user equipment to report scheduling information for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the apparatus including a plurality of priority queues having same priorities, for storing packet data relating to at least one service; and a protocol data unit generator for generating a protocol data unit containing a header part and a payload part for the uplink packet data service, receiving packet data outputted from the priority queues, inserting the scheduling information into the header part, inserting packet data into the payload part, and transmitting the protocol data unit.

In order to accomplish the aforementioned objects, according to yet a further aspect of the present, there is provided a Node B for scheduling an uplink packet data service from a user equipment in a mobile communication system, the Node B including a reception unit for a protocol data unit containing a header part and a payload part for the uplink packet data service; a header detection unit for detecting scheduling information for the uplink packet data service from the header part of the protocol data unit and detecting packet data from the payload part of the protocol data unit; a scheduler for generating scheduling assignment information for the uplink packet data service according to the scheduling information; and a transmission unit for transmitting the scheduling assignment information to the user equipment.

BRIEF DESCRIPTION OF THE DRAWINGS

The above and other objects, features and advantages of the present invention will be more apparent from the following detailed description taken in conjunction with the accompanying drawings, in which:

FIG. 1A is a view showing variations of an uplink radio resource of a Node B when a Node B control scheduling is not used;

FIG. 1B is a view showing variations of an uplink radio resource of a Node B when a Node B control scheduling is used;

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Hereinafter, a preferred embodiment according to the present invention will be described with reference to the accompanying drawings. In the following description of the present invention, a detailed description of known functions and configurations incorporated herein will be omitted when it may make the subject matter of the present invention unclear.

A Universal Mobile Telecommunication Service (hereinafter, referred to as a UMTS), one of the 3rd Generation Partnership Project (3GPP) mobile communication services, is based on a communication standard of a Global System for Mobile Communication (hereinafter, referred to as a GSM) and a General Packet Radio Service (GPRS) employs a wideband CDMA technology, in contrast to the GSM employing a Time Division Multiple Access (TDMA).

A UMTS Terrestrial Radio Access Network (hereinafter, referred to as a UTRAN) includes Node Bs containing a plurality of cells and a Radio Network Controller (hereinafter, referred to as a RNC) managing radio resources of the Node Bs.

An interface between a UE and a RNC is called an Uu interface and is classified as a control plane for exchanging control and signaling signals and a user plane for transmitting data traffic. The control plane includes a radio resource control (RRC) layer, a radio link control (RLC) layer, a media access control (MAC) layer, and a physical (hereinafter, referred to as a PHY) layer. Further, the user plane includes a packet data control protocol (PDCP) layer, an RLC layer, a MAC layer, and a PHY layer. Herein, the PHY layer is located in each cell and the layers between a MAC layer and a RRC layer are located in a RNC.

Particularly, a portion related to a user plane in a MAC layer is called a MAC-d and a portion related to a control plane is called a MAC-c. User data to be transmitted through a dedicated transport channel is generated into a transmission block having a desired size through a MAC-d layer. When the user data is transmitted through an EUDCH, the transmission block passes through a MAC-eu portion in the MAC layer. A MAC-eu layer performs a process a Node B control scheduling, HARQ, etc., for an EUDCH before transmitting data sent from a MAC-d layer to a PHY layer.

FIG. 5 is a view showing a structure of a MAC-eu layer of a UE transmitting an EUDCH according to a preferred embodiment of the present invention.

The MAC-eu layer 500 of the UE includes a priority queue distributor 502 and a priority queues (PQs) 504, and receives data to be transmitted to a Node B from a MAC-d layer 518. The received data is sent to the priority queue distributor 502 of the MAC-eu layer 500. The priority queue distributor 502 determines a priority for the received data and buffers the data in a priority queue, which corresponds to the determined priority, from among the priority

queues 504.

The priority queues 504 are used in storing data according to a priority of a service to be provided and have inherent queue identifiers (hereinafter, referred to as QIDs) respectively. That is, each of the priority queues 504 is related to at least one service and stores data having different priorities. FIG. 5 shows two priority queues 504, but the number of the priority queues 504 is randomly determined by a MAC control signal 516 according to the type and number of services being provided. That is, when a priority for data to be transmitted to the Node B is classified as multiple steps, the number of the priority queues 504 increases. The priority is determined according to a transmission time point (i.e., required delay) at which data is to be transmitted to the Node B. That is, data which must be transmitted to the Node B within a rapid time period has a high priority, and data which does not have the necessity of being transmitted to the Node B within a rapid time period has a low priority.

The priority queue distributor 502 determines a priority for the received data and sends the data to one of the priority queues 504 according to the determined priority. In this way, data having the same priority is sent to the same priority queue. The priority queues 504 store the received data before a resource is assigned by the scheduling of the Node B.

In order to request a scheduling assignment from the Node B, the MAC-*eu* layer 500 transmits scheduling information, which contain a buffer status representing the amount of the data stored in the priority queues 504 and a channel status representing the transmission quality of an uplink, through an EUDCH related uplink 510. When the Node B transmits scheduling assignment information to the UE through an EUDCH related downlink 514, a Transport format combination (hereinafter, referred to as a TFC) selection part 508 determines a TFC by means of the scheduling assignment information, reads the data from the priority queues 504 by means of the determined TFC, and transmits the read data through an EUDCH 512. Herein, the UE first transmits data having a high priority stored in the priority queues 504. Therefore, a

transmission time can be differently designated according to the priority. Meanwhile, an HARQ entity 506 interprets an ACK/NACK received through the related downlink 514 with respect to the transmitted data, discards data stored in a corresponding priority queue when an ACK is received, and retransmits data stored in a corresponding priority queue when a NACK is received.

FIG. 6 is a view illustrating an operation by which two UEs request a scheduling assignment to a Node B according to one embodiment of the present invention.

In FIG. 6, the UE 610 includes two priority queues 612 and 614 and the UE 620 includes one priority queue 622. The priority queue 612 of the UE 610 has a priority higher than that of the priority queue 614, and the priority queue 622 of the UE 620 has the same priority as that of the priority queue 612 of the UE 610. The priority queue 612 of the UE 610 stores 100 bits of data, the priority queue 614 of the UE 610 stores 300 bits of data, and the priority queue 622 of the UE 620 stores 300 bits of data. The Node B 600 has a radio resource capable of receiving only 450 bits of data.

Referring to FIG. 6, the UEs 610 and 620 transmit buffer status information 630 and 632 representing the amount of data to be transmitted to the Node B 600. That is, the UE 610 transmits the buffer status information 630 corresponding to 400 bits to the Node B 600, and the UE 620 transmits the buffer status information 632 corresponding to 300 bits to the Node B 600. Herein, when uplink channel conditions of the UEs 610 and 620 are identical to each other, the Node B 600 transmits scheduling assignment information 640, which enables only 200 bits to be transmitted, to the UE 610, and scheduling assignment information 642, which enables only 150 bits to be transmitted, to the UE 620.

The UE 610 determines a TFC by means of the scheduling assignment information 640, transmits data through an EUDCH by means of the determined TFC. That is, according to a priority, 100 bits of data on standby in the priority queue 612 are first transmitted, and then 100 bits of data on standby in the

priority queue 614 are transmitted. The UE 620 also determines a TFC by means of the scheduling assignment information 642, transmits data through an EUDCH by means of the determined TFC. That is, 150 bits of data on standby in the priority queue 622 are transmitted.

Herein, although the priority queue 612 of the UE 620 has a priority higher than that of the priority queue 614 of the UE 610, all data in the standby state are not transmitted. That is, when there exists one UE requesting the scheduling assignment information to the Node B 600, data in the standby state are transmitted according to priority. However, when there exists two or more UEs requesting the scheduling assignment information to the Node B 600, there occurs a problem in that data having a higher priority are transmitted later than data having a low priority.

FIG. 7 is a view illustrating a preferred embodiment of the present invention for solving the problem in FIG. 6. In FIG. 7, UEs 710 and 720 transmit not only the amount of data but also information on a priority to a Node B 700 at the same time.

Referring to FIG. 7, the UE 710 includes two priority queues 712 and 714 and the UE 720 includes one priority queue 722. The priority queue 712 of the UE 710 has a priority higher than that of the priority queue 714, and the priority queue 722 of the UE 720 has the same priority as that of the priority queue 712 of the UE 710. The priority queue 712 of the UE 710 stores 100 bits of data, the priority queue 714 of the UE 710 stores 300 bits of data, and the priority queue 722 of the UE 720 stores 300 bits of data.

The UEs 710 and 720 transmit buffer status information 730 and 732 containing the amount of data to be transmitted and information on a priority to the Node B 700. That is, the UE 710 transmits the buffer status information 730 containing the amount of data corresponding to 400 bits and a QID representing a priority to the Node B 700. That is, the buffer status information 730 signifies that the amount of data corresponding to a Priority 1 is 100 bits and the amount of data corresponding to a Priority 2 is 300 bits. Further, the UE 720 transmit

the buffer status information 732 containing the amount of data corresponding to 300 bits and a QID representing a priority to the Node B 700. Herein, when uplink channel conditions of the UEs 710 and 720 are identical to each other, the Node B 700 transmits scheduling assignment information 740 and 742 to the UEs 710 and 720 in consideration of the priority. That is, the Node B 700 transmits scheduling assignment information 740, which enables only 100 bits to be transmitted, to the UE 710, and scheduling assignment information 742, which enables only 250 bits to be transmitted, to the UE 720.

The UE 710 determines a TFC by means of the scheduling assignment information 740, transmits data through an EUDCH by means of the determined TFC. That is, 100 bits of data on standby in the priority queue 712 are transmitted according to priority. The UE 720 also determines a TFC by means of the scheduling assignment information 742, transmits data through an EUDCH by means of the determined TFC. That is, 250 bits of data on standby in the priority queue 722 are transmitted. In this way, the UEs 710 and 720 can first transmit data having a high priority.

FIG. 8 is a view showing a structure of a MAC-eu scheduling controller of a UE according to a preferred embodiment of the present invention.

Referring to FIG. 8, the scheduling controller 800 includes a configuration controller 804, a priority queue (PQ) controller 802, and a TFC selector 806. The priority queue controller 802 receives buffer payload information 810 and 812 from priority queues, and the buffer payload information 810 and 812 represent the amount of data on standby in each priority queue. In FIG. 8, it is assumed that N number of priority queues exist. The buffer payload information 810 represents buffer payload information sent from a priority queue 1 and the buffer payload information 812 represents buffer payload information sent from a priority queue n. Further, the priority queue controller 802 receives queue information 814 from the configuration controller 804. Herein, the queue information 814 is configuration information of priority queues, and it is related to the sizes and the number of memories of priority

queues.

The priority queue controller 802 transmits a buffer status information 826 containing a QID regarding a priority of a corresponding buffer payload information 810 and 812 to the Node B through an EUDCH tx part 828.

The TFC selector 806 receives scheduling assignment information 820 through a shared control channel for EUDCH (E-SCCH), a buffer status information 816 about priority queues from the priority queue controller 802, and scheduling configuration information from the configuration controller 804. The scheduling configuration information contains priorities of priority queues, transport format combination set, etc. The TFC selector 806 determines a TFC by means of the buffer status information 816 and the scheduling assignment information 820. The TFC is determined so that data stored in a priority queue having a high priority is first transmitted.

The TFC selector 806 transmits the determined TFC to a dedicated physical data channel for EUDCH (hereinafter, referred to as a E-DPDCH) tx part 824. The E-DPDCH tx part 824 transmits EUDCH packet data by means of the received TFC. Herein, the determined TFC is transmitted to a dedicated physical control channel for EUDCH (hereinafter, referred to as a E-DPCCH) tx part 822. The E-DPCCH tx part 822 transmits control information containing the TFC together with the EUDCH packet data at the same time point. Also, the TFC is transmitted to the priority queue controller 802 over a scheduling information 818. The priority queue controller 802 understands by means of the TFC the priority queue in which transmitted data has been in a standby state by means of the TFC, and renews the buffer status of the priority queues.

FIG. 9 is a flowchart illustrating an operation of a MAC-eu scheduling controller according to a preferred embodiment of the present invention.

Referring to FIG. 9, in step 900, the scheduling controller determines whether or not new data has arrived at priority queues by buffer payload information sent from priority queues. Further, the scheduling controller determines a priority queue from which the buffer payload information has been

transmitted, thereby understanding the amount and priority of data transmitted to the priority queues. When the new data has arrived at the priority queues, step 902 is performed. In contrast, when the new data has not arrived at the priority queues, the process returns to step 900.

In step 902, the scheduling controller transmits buffer status information containing the buffer payload information and buffer status information containing a QID representing a priority relating to the buffer payload information to a Node B.

In step 904, the scheduling controller determines whether or not scheduling assignment information is received from the Node B. The scheduling assignment information contains information on a maximum data rate capable of being used by a UE and a permission timing. From the result of the determination, when the scheduling assignment information has been received from the Node B, step 906 is performed. In contrast, when the scheduling assignment information has not been received from the Node B, the process returns to step 904.

In step 906, the scheduling controller determines a TFC within a data rate assigned by the scheduling assignment information. In determining the TFC, the scheduling controller enables data having a high priority to be first transmitted in consideration of the priority of the data transmitted to the priority queues. In step 908, the scheduling controller controls the data transmitted to the priority queues to be transmitted by means of the determined TFC. The MAC-eu layer generates a MAC-eu protocol data unit (PDU) containing data read from a corresponding priority queue by the control command of the scheduling controller, and transmits the generated MAC-eu PDU through the E-DPDCH. Further, the scheduling controller transmits the determined TFC through the E-DPCCH, and renews information on the changed buffer status. The renewed buffer status is transmitted through an EUDCH.

FIG. 10 is a view illustrating a MAC-eu signaling between a UE and a Node B according to a preferred embodiment of the present invention. As

shown in FIG. 10, the MAC-eu layer 1000 of the UE transmits a buffer status message to the MAC-eu layer 1002 of the Node B. The buffer status information contains a QID and a buffer payload of a priority queue as described above.

FIG. 11 is a view showing a construction of a MAC-eu PDU containing buffer status information according to a preferred embodiment of the present invention. As shown in FIG. 11, the MAC-eu PDU includes a MAC-eu header 1100 contained in a header part and a plurality of MAC-eu service data units 1102 (SDUs) contained in a payload part. Information contained in the MAC-eu header 1100 is as follows:

A version flag (VF) representing the version of a MAC-eu PDU format.

A QID identifying of a priority queue from which a MAC-eu SDU is outputted, constructed of 3 bits.

A transmission sequence number (TSN) for realigning a MAC-eu SDU according to a priority, constructed of 5 to 6 bits.

An SID_k representing the size of MAC-d SDUs belonging to an xth MAC-eu SDU set from among the sets of the MAC-d SDUs constituting a MAC-eu PDU, constructed of 2 to 3 bits.

An N_k representing the number of MAC-d PDUs belonging to a MAC-eu SDU set, constructed of 7 bits.

A flag (F). When flag (F) is set to 1, the next field is a MAC-eu PDU. When F (flag) is set to 0, the next field is an SID.

A QID map representing an identifier of a priority queue in which data exists, and a bit number is assigned for as many as the number of priority queues. A numeral 1 represents existence of data and a numeral 0 represents absence of data.

A buffer payload represents the size of data stored in priority queues in which the value of the QID map is 1, and a bit number according to the length of the QID map is assigned.

FIG. 12 is a view showing a structure of a MAC-eu scheduler of a Node

B according to a preferred embodiment of the present invention.

Referring to FIG. 12, the scheduler 1200 includes a UE status analyzer 1202 and a resource controller 1204. The UE status analyzer 1202 receives buffer status messages and channel status messages 1210, 1212, and 1214 of UEs UE#1 to UE#N located in a cell area managed by the Node B. The UE status analyzer 1202 receives buffer status information according to a priority queue contained in a MAC-eu header of a MAC-eu PDU transmitted from each UE and estimates the amount of data stored in a priority queue of each UE. Further, the UE status analyzer 1202 transmits an estimated value for the amount of data in each UE to the resource controller 1204.

The resource controller 1204 calculates an ROT to be assigned to a specific UE in consideration of the estimated value for the amount of data in each UE, the channel status, and a target ROT provided from an RNC through a Node B application protocol (NBAP), and determines a maximum allowed data rate to be assigned to the UE in consideration of the priorities of the priority queues of the UE. Further, when the TFC is determined, the size of data which can be transmitted from the UE and an offset of transmission power are determined according to the TFC. The maximum allowed data rate to be assigned to the UE is contained in maximum allowed TFC information 1220 and 1222 and then transmitted to the UE by E-SCCH tx parts 1224 and 1226.

FIG. 13 is a flowchart showing an operation of a MAC-eu scheduler of a Node B according to a preferred embodiment of the present invention.

Referring to FIG. 13, in step 1300, the scheduler determines whether or not a MAC-eu PDU containing scheduling information has been received from a UE. The scheduling information contains buffer payload information of each UE and information on a priority of each buffer. From the result of the determination, when the scheduling information has been received, step 1302 is performed. In contrast, when the scheduling information has not been received, the process returns to step 1300.

In step 1302, the scheduler determines a maximum allowed data rate to

be assigned to the UE on the basis of the buffer status information and the channel status information received from the UE. The maximum allowed data rate is determined in consideration of the target ROT provided from the RNC and a priority of data to be transmitted by the UE. Further, the maximum allowed data rate is transmitted to the UE through a control channel relating to an EUDCH in step 1304.

FIG. 14 is a block diagram illustrating an apparatus for performing a transmission/reception operation by a UE according to a preferred embodiment of the present invention. First, an operation of a reception side receiving scheduling assignment information will be described.

Referring to FIG. 14, a signal received in an antenna passes through a radio frequency (RF) unit 1442, is converted into a baseband signal, and then is inputted to a descrambler 1400. The descrambler 1400 descrambles the baseband signal by a scrambling code $S_{dl,n}$. The descrambled signal is sent to a despreader 1402. In order to perform dechannelization for the descrambled signal, the despreader 1402 multiplies the descrambled signal by a channelization code C_{es} , and sends the dechannelized signal to a demodulation unit 1404. The dechannelized signal is demodulated by the demodulation unit 1404 and decoded by a decoding unit 1406. Then, an E-SCCH detection unit 1408 detects the scheduling assignment information from the decoded signal, and the scheduling assignment information contains maximum allowed TFC information 1410 assigned to the UE.

The maximum allowed TFC information 1410 is transmitted to a MAC-eu scheduling controller 1412 and the MAC-eu scheduling controller 1412 determines a TFC by means of the maximum allowed TFC information 1410. The TFC is determined considering information on a priority of data on standby in priority queues 1422 and 1424. For this reason, the priority queues 1422 and 1424 store data relating to one or more services having different priorities, and transmit a QID and buffer payload information to the MAC-eu scheduling controller 1412 periodically or whenever new data is stored. The MAC-eu

scheduling controller 1412 transmits information on the determined TFC to an E-DPCCH generator 1414. The E-DPCCH generator 1414 generates a control signal containing other control information and the TFC. The generated control signal is coded by a coding unit 1416 and the coded signal is modulated by a modulation unit 1418. Then, the modulated signal is subjected to channelization by a spreader 1420 with a channelization code C_{ec} and then is transmitted to a multiplexer 1438.

A MAC-eu PDU generator 1428 performs two functions. First, the MAC-eu PDU generator 1428 includes the QID and the buffer status information sent from the MAC-eu scheduling controller 1412 into a MAC-eu header. Secondly, the MAC-eu PDU generator 1428 appends the MAC-eu header to the data on standby in the priority queues 1422 and 1424 by means of the TFC sent from the MAC-eu scheduling controller 1412, and generates a MAC-eu PDU. The MAC-eu PDU is coded by a coding unit 1430 and rate-matched by a rate matching unit 1432. The rate-matched signal is modulated by a modulation unit 1434 and the modulated signal is subjected to channelization by a spreader 1436 with a channelization code C_e . The channel coded data is transmitted to multiplexer 1438. The multiplexer 1438 multiplexes signals provided from the spreaders 1420 and 1436 and signals from other channels. The multiplexed signal is scrambled by a scrambler 1440 with a scrambling code $S_{dpch,n}$ and is converted into an RF signal by an RF unit 1444. Then, the RF signal is transmitted to the Node B through an antenna.

FIG. 15 is a block diagram illustrating an apparatus for performing a transmission/reception operation by a Node B according to a preferred embodiment of the present invention. First, an operation of a reception side receiving scheduling information will be described. The reception part of the Node B has N number of reception paths 1540 and 1542 corresponding to each of N number of UEs performing an uplink packet data service. Herein, an operation of the reception path 1540 corresponding to a UE#1 will be described, but it is apparent to those who skilled in the art that the other reception paths also

perform the same operations.

Referring to FIG. 15, a signal received in an antenna passes through an RF unit 1538, is converted into a baseband signal, and then is inputted to a descrambler 1518. The descrambler 1518 descrambles the baseband signal by a scrambling code $S_{dpch,n}$. The descrambled signal is sent to despreaders 1520 and 1522 and then is dechannelized into an E-DPCCH signal and an E-DPDCH signal. The E-DPCCH signal for which channelization has been performed by the despreaders 1522 with a channelization code C_{cc} is demodulated by a demodulation unit 1524, and then is decoded by a decoding unit 1526. A control information detector 1527 detects control information necessary in receiving EUDCH data from data decoded by the decoding unit 1526, and the control information contains modulation information, etc., of the EUDCH data.

The E-DPDCH signal for which channelization has been performed by the despreaders 1520 with a channelization code C_c is demodulated by a demodulation unit 1528 with the modulation information detected by the control information detection unit 1527. The demodulated signal is subjected to a rate-dematching by a rate-dematching unit 1530 and then is decoded by a decoding unit 1532.

A MAC-eu header detection unit 1534 separates buffer status information in a header and data in a payload from a MAC-eu PDU sent from the decoding unit 1532. Herein, when a QID map in a MAC-eu header has values other than 0, the MAC-eu header detection unit 1534 detects buffer status information 1516 contained in the MAC-eu header to transmit the detected buffer status information 1516 to a MAC-eu scheduler 1514. Herein, the buffer status information 1516 includes at least one QID and buffer payload information. Further, the MAC-eu header detection unit 1534 separates MAC-eu SDUs, except for the MAC-eu header, from the MAC-eu PDU and transmits the MAC-eu SDUs to reordering buffers of an upper layer. The reordering buffers are located in an RNC, correspond to priority queues of a UE-side, and align received MAC-eu SDUs according to TSNs of the MAC-eu SDUs.

The MAC-eu scheduler 1514 generates a maximum allowed TFC information 1512 for each UE by means of the buffer status information 1516 and other scheduling information, and transmits the generated maximum allowed TFC information 1512 to an E-SCCH generator 1510. The maximum allowed TFC is determined considering a priority of data contained the buffer status information to be transmitted. The E-SCCH generator 1510 generates scheduling assignment information for the maximum allowed TFC information 1512. The scheduling assignment information is coded by a coding unit 1508 and then is modulated by a modulation unit 1506. The signal modulated by the modulation unit 1506 is subjected to channelization by a spreader 1504 with a channelization code C_{es} , and then is transmitted to a multiplexer 1502. The multiplexer 1502 multiplexes the received signal together with other downlink channel signals. The multiplexed signal is scrambled by a scrambler 1500 with a scrambling code $S_{dl,n}$ and is converted into an RF signal by an RF unit 1536. Then, the RF signal is transmitted to a UE through an antenna.

As described above, in the present invention, when a UE transmits data having required different priorities through an enhanced uplink channel at the same time, a Node B control scheduling reflects the priorities of the data. For this, the UE transmits buffer status information of a priority queue corresponding to quality of service, and a Node B can perform scheduling by means of the received buffer status information of the priority queue. Accordingly, the present invention provides a differentiated service according to required priorities, thereby satisfying the requirements of users.

While the invention has been shown and described with reference to certain preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention as defined by the appended claims.

1. A method for reporting a status of a buffer storing packet data to be transmitted by a user equipment (UE) for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the method comprising the steps of:

a) storing packet data having a priority corresponding to a plurality of priority queues relating to at least one service; and

b) transmitting buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues.

2. The method as claimed in claim 1, wherein, in step b), the buffer status information is inserted into a header part of a protocol data unit (PDU) for the uplink packet data service and the packet data is inserted into a payload part of the protocol data unit, and then the protocol data unit is transmitted.

3. The method as claimed in claim 2, wherein the buffer status information includes:

a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;

an identifier of at least one priority queue represented by the queue identifier map; and

a size of the data stored in at least one priority queue represented by the queue identifier map.

4. The method as claimed in claim 2, wherein the header part is a media access control (MAC) signaling header for an enhanced uplink dedicated channel (EUDCH).

5. The method as claimed in claim 1, further comprising a step of receiving scheduling assignment information corresponding to the buffer status from a Node B providing the service to the user equipment, first reading packet data having a high priority from the priority queues according to the scheduling assignment information, and transmitting the read packet data.

6. A method which enables a user equipment to report scheduling information for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the method comprising the steps of:

generating a protocol data unit including a header part and a payload part for the uplink packet data service; and

inserting the scheduling information into the header part, inserting packet data for the uplink packet data service into the payload part, and transmitting the protocol data unit.

7. The method as claimed in claim 6, wherein the scheduling information contains queue identifiers representing a plurality of priority queues having inherent priorities and relating to at least one service, and buffer payload information representing an amount of packet data stored in the priority queues.

8. The method as claimed in claim 7, wherein the buffer payload information includes:

a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;

an identifier of at least one priority queue represented by the queue identifier map; and

a size of the data stored in at least one priority queue represented by the queue identifier map.

9. The method as claimed in claim 6, wherein the header part is a media access control signaling header for an enhanced uplink dedicated channel.

10. The method as claimed in claim 7, further comprising a step of receiving scheduling assignment information corresponding to the scheduling information from a Node B providing the service to the user equipment, and first transmitting packet data having a high priority according to the scheduling assignment information.

11. An apparatus for reporting a status of a buffer storing packet data to be transmitted by a user equipment for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the apparatus comprising:

a plurality of priority queues having same priorities, for storing packet data relating to at least one service;

a scheduling controller for generating buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues; and

transmission unit for transmitting the buffer status information.

12. The apparatus as claimed in claim 11, wherein the transmission unit comprises a protocol data unit generator for generating a protocol data unit containing a header part and a payload part for the uplink packet data service, inserting the buffer status information into the header part, and inserting packet data read from the priority queues into the payload part.

13. The apparatus as claimed in claim 12, wherein the buffer status information includes:

a queue identifier map representing at least one priority queue, in which

the stored data exists, from among the priority queues;

an identifier of at least one priority queue represented by the queue identifier map; and

a size of the data stored in at least one priority queue represented by the queue identifier map.

14. The apparatus as claimed in claim 12, wherein the header part is a media access control signaling header for an enhanced uplink dedicated channel.

15. The apparatus as claimed in claim 11, wherein the scheduling controller receives scheduling assignment information corresponding to the buffer status from a Node B providing the service to the user equipment, and controls the priority queues to first output packet data having a high priority according to the scheduling assignment information.

16. An apparatus which enables a user equipment to report scheduling information for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the apparatus comprising:

a plurality of priority queues having same priorities, for storing packet data relating to at least one service; and

a protocol data unit generator for generating a protocol data unit containing a header part and a payload part for the uplink packet data service, receiving packet data outputted from the priority queues, inserting the scheduling information into the header part, inserting packet data into the payload part, and transmitting the protocol data unit.

17. The apparatus as claimed in claim 16, wherein the scheduling information contains queue identifiers representing the priority queues having inherent priorities and relating to at least one service, and buffer payload

information representing an amount of packet data stored in the priority queues.

18. The apparatus as claimed in claim 17, wherein the scheduling information includes:

a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;

an identifier of at least one priority queue represented by the queue identifier map; and

a size of the data stored in at least one priority queue represented by the queue identifier map.

19. The apparatus as claimed in claim 16, wherein the header part is a media access control signaling header for an enhanced uplink dedicated channel.

20. The apparatus as claimed in claim 17, further comprising a scheduling controller for receiving scheduling assignment information corresponding to the scheduling information from a Node B providing the service to the user equipment, and controlling the priority queues to first output packet data having a high priority according to the scheduling assignment information.

21. A Node B apparatus for scheduling an uplink packet data service from a user equipment in a mobile communication system, the Node B comprising:

a reception unit for a protocol data unit containing a header part and a payload part for the uplink packet data service;

a header detection unit for detecting scheduling information for the uplink packet data service from the header part of the protocol data unit and detecting packet data from the payload part of the protocol data unit;

a scheduler for generating scheduling assignment information for the uplink packet data service according to the scheduling information; and

a transmission unit for transmitting the scheduling assignment information to the user equipment.

22. The Node B apparatus as claimed in claim 21, wherein the scheduling information contains queue identifiers representing the priority queues having inherent priorities and relating to at least one service, and buffer payload information representing an amount of packet data stored in the priority queues.

23. The Node B apparatus as claimed in claim 22, wherein the payload information includes:

a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;

an identifier of at least one priority queue represented by the queue identifier map; and

a size of the data stored in at least one priority queue represented by the queue identifier map.

24. The Node B apparatus as claimed in claim 21, wherein the header part is a media access control signaling header for an enhanced uplink dedicated channel.

1 . ABSTRACT

A method and an apparatus for reporting a buffer status of a buffer storing packet data to be transmitted by a user equipment for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service are disclosed. A user equipment stores packet data having a priority corresponding to a plurality of priority queues having inherent priorities and relating to at least one service, and transmits buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues. Herein, the user equipment inserts the buffer status information into a header part of a protocol data unit for the uplink packet data service, inserts the packet data into a payload part of the protocol data unit, and then transmits the protocol data unit.

A method and an apparatus for reporting a buffer status of a buffer storing packet data to be transmitted by a user equipment for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service are disclosed. A user equipment stores packet data having a priority corresponding to a plurality of priority queues having inherent priorities and relating to at least one service, and transmits buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues. Herein, the user equipment inserts the buffer status information into a header part of a protocol data unit for the uplink packet data service, inserts the packet data into a payload part of the protocol data unit, and then transmits the protocol data unit.

PRIORITY

[0001] This application claims priority to an application entitled "Method And Apparatus For Scheduling Assignment Of Uplink Packet Transmission In Mobile Telecommunication System" filed in the Korean Intellectual Property Office on Aug. 26, 2003 and assigned Serial No. 2003-59172, the contents of which are hereby incorporated by reference.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The present invention relates to a mobile telecommunication system, and more particularly to a method and an apparatus for efficiently transceiving scheduling assignment information for transmitting packet data through an uplink (UL).

[0004] 2. Description of the Related Art

[0005] An asynchronous Wideband Code Division Multiple Access (hereinafter, referred to as a WCDMA) communication system employs an Enhanced Uplink Dedicated Channel (hereinafter, referred to as an EUDCH or E-DCH) in order to support a high speed packet data service through an uplink. The EUDCH is a channel proposed to improve the performance of a packet transmission in an uplink communication in an asynchronous code division multiple access communication system. The EUDCH-related technology includes new technologies for a more reduced Transmission Time Interval (TTI) together with the Adaptive Modulation and Coding (AMC) method and the Hybrid Automatic Retransmission Request (HARQ) method already used in a High Speed Downlink packet access (HSDPA). Further, a Node B control scheduling of an uplink channel is used. The Node B control scheduling for the uplink is very different from a scheduling for a downlink.

[0006] Since uplink signals transmitted from a plurality of user equipments (hereinafter, referred to as UEs) do not maintain orthogonality between the uplink signals, the uplink signals function as interference signals between themselves. Therefore, as the number of uplink signals received in the Node B increase, the number of interference signals for uplink signals transmitted from a specific UE also increases. Accordingly, as the number of the interference signals with respect to the uplink signals transmitted from the specific UE increases, the reception performance of the Node B is reduced. In order to overcome such a problem, uplink transmission power may be increased. However, an uplink signal having increased transmission power also functions as an interference signal with respect to another signal. Accordingly, the Node B limits the number of a receivable uplink signals while ensuring its own reception performance. Equation (1) represents the number of the receivable uplink signal while the reception performance of the Node B is ensured.

$$ROT = \frac{I_o}{N_o} \quad (1)$$

[0007] In Equation (1), I_o represents an entire reception wideband power spectral density of the Node B and N_o represents a thermal noise power spectral density of the Node B. Accordingly, the ROT is a radio resource capable of being assigned by the Node B for the EUDCH packet data service in an uplink.

[0008] FIGS. 1A and 1B show variations of an uplink radio resource assigned by a Node B. As shown in FIGS. 1A and 1B, the uplink radio resource assigned by the Node B is obtained by the sum of inter-cell interference (hereinafter, referred to as an ICI), voice traffic, and EUDCH packet traffic.

[0009] FIG. 1A shows variation of the total ROT when Node B scheduling is not used. Since scheduling is not performed for the EUDCH packet traffic, the total ROT grows larger than a target ROT when a plurality of UEs transmit the packet data at a high data rate at the same time. Herein, the reception performance of the uplink signal is reduced.

[0010] FIG. 1B shows variation of the total ROT when Node B scheduling is used, thereby preventing the multiple UEs from transmitting the packet data at a high data rate at the same time. That is, the Node B scheduling enables a high data rate to be permitted to a specific UE and a low data rate to be permitted to other UEs, thereby preventing the total ROT from exceeding the target ROT. Accordingly, Node B scheduling can always maintain constant reception performance.

[0011] The Node B notifies each UE of information regarding whether or not EUDCH data can be transmitted by means of a request data rate of UEs using the EUDCH or channel status information representing transmission quality of an uplink. Also, the Node B adjusts the EUDCH data rate. Further, in order to improve the performance of a mobile communication system, the Node B scheduling assigns the data rate to the UEs so that the total ROT of the Node B does not exceed the target ROT. For example, the Node B may assign a low data rate to a UE in a position remote from the Node B and a high data rate to a UE in a position near to the Node B.

[0012] FIG. 2 is a view illustrating a basic concept regarding circumstances in which a Node B scheduling is used in an EUDCH. In FIG. 2, Node B 200 supports the EUDCH and reference numerals 210, 212, 214, and 216 represent UEs transmitting the EUDCH. When a data rate of a certain UE increases, reception power received in the Node B 200 from the UE increases. Accordingly, a ROT of the UE occupies a large portion of the total ROT. In contrast, when a data rate of another UE is reduced, reception power received in the Node B 200 from another UE is reduced. Accordingly, a ROT of another UE occupies a small portion of the total ROT. The Node B 200 performs the Node B scheduling for the EUDCH packet data in consideration of the relation between the data rates and a radio resource requested by the UEs 210, 212, 214, and 216.

[0013] In FIG. 2, the UEs 210, 212, 214, and 216 transmit the packet data with different uplink transmission powers from each other according to the distance between the Node B 200 and the UEs 210, 212, 214, and 216. UE 210, in the furthest position from the Node B 200, transmits the packet data with the highest transmission power 220 of an uplink channel. In contrast, UE 214, in the nearest position to the Node B 200, transmits the packet data with the lowest transmission power 224 of an uplink channel. In order to improve the performance of a mobile communication system while maintaining the total ROT and reducing an ICI for another cell, the Node B performs scheduling so that the transmission power intensity of the uplink channel is inversely proportional to the data rate, thereby assigning a relatively lower data rate to the UE 210 having the highest transmission power of an uplink channel and a relatively higher data rate to the UE 214 having the lowest transmission power of an uplink channel.

[0014] FIG. 3 is a flow diagram illustrating a basic transmission/reception procedure between a UE 302 transmitting an EUDCH and a Node B 301 including the UE 302.

[0015] In step 303, a setup of an EUDCH is accomplished between the Node B 301 and the UE 302. The setup step includes a transmission step of messages through a dedicated transport channel. When the EUDCH setup is accomplished, the UE 302 informs the Node B 301 of scheduling information at step 304. The scheduling information may include UE transmission power information enabling uplink channel information to be understood, extra information of transmission power capable of being transmitted by a UE, and the amount of data stored in a buffer of a UE that must be transmitted.

[0016] In step 311, the Node B 301 monitors the scheduling information of the UE 302 and schedules the UE 302. When the Node B 301 determines to permit an uplink data transmission to the UE 302 in step 311, the Node B 301 transmits scheduling assignment information containing an assigned data rate and a transmission timing to the UE 302 in step 305. In step 312, the UE 302 determines a Transport Format (TF) such as a data rate for a EUDCH transmission based on the scheduling assignment information and chooses a Transport Format Resource Indicator (TFRI) indicating the TF. In step 307, the UE 302 transmits EUDCH data by means of the TFRI. Further, the TFRI, which is related information representing the TF of the EUDCH data, is transmitted to the Node B 301 in step 306 together with the EUDCH data. In step 313, the Node B 301 determines whether or not an error exists in the TFRI and the EUDCH data. As a result of the determination, when the error exists in at least one of the TFRI and the EUDCH data, the Node B 301 transmits a NACK to the UE 302 through an ACK/NACK channel, in step 308. In contrast, when any error does not exist in the TFRI and the EUDCH data, the Node B 301 transmits an ACK to the UE 302 through an ACK/NACK channel, in step 308.

[0017] The Node B 301 decides a data rate to be assigned to a UE on the basis of the scheduling information. Herein, the Node B 301 assigns a proper data rate and transmission timing to multiple UEs using an EUDCH. Further, in the scheduling, the Node B 301 assigns a resource to each UE in order to prevent a ROT value of an uplink from exceeding a target ROT value. Herein, the Node B 301 assigns many

resources to a UE having a good channel condition in order to improve the entire performance of a system.

[0018] FIG. 4 is a view showing the types of data transmitted from a UE to a Node B for an uplink packet data service.

[0019] As shown in FIG. 4, a UE 400 can transmit voice and image traffic, packet data, data regarding a game, etc., to a Node B 402 through an EUDCH. The data transmitted from the UE as described above requires different quality of service (QoS) according to the types of the data. Accordingly, it is necessary to provide a method by which the Node B 402 performs a scheduling and assigns a radio resource according to quality of service required by data to be transmitted

SUMMARY OF THE INVENTION

[0020] Accordingly, the present invention has been made to solve the above-mentioned problems occurring in the prior art, and it is an object of the present invention is to provide a method and an apparatus for assigning a radio resource according to quality of service required by data to be transmitted.

[0021] It is another object of the present invention is to provide a method and an apparatus for assigning many radio resources with respect to data requesting high quality of service and a few radio resources with respect to data requesting low quality of service.

[0022] It is further object of the present invention is to provide a method and an apparatus for efficiently using a radio resource of a mobile communication system by assigning radio resources different from each other according to quality of service.

[0023] In order to accomplish the aforementioned objects, according to one aspect of the present invention, there is provided a method for reporting status of a buffer storing packet data to be transmitted by a user equipment for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the method including storing packet data having a priority corresponding to a plurality of priority queues having inherent priorities and relating to at least one service; and transmitting buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues.

[0024] In order to accomplish the aforementioned objects, according to another aspect of the present invention, there is provided a method which enables a user equipment to report scheduling information for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the method including generating a protocol data unit including a header part and a payload part for the uplink packet data service; and inserting the scheduling information into the header part, inserting packet data for the uplink packet data service into the payload part, and transmitting the protocol data unit.

[0025] In order to accomplish the aforementioned objects, according to a further aspect of the present invention, there is provided an apparatus for reporting status of a buffer

storing packet data to be transmitted by a user equipment for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the apparatus including a plurality of priority queues having same priorities, for storing packet data relating to at least one service; a scheduling controller for generating buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues; and a transmission unit for transmitting the buffer status information.

[0026] In order to accomplish the aforementioned objects, according to still another aspect of the present invention, there is provided an apparatus which enables a user equipment to report scheduling information for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the apparatus including a plurality of priority queues having same priorities, for storing packet data relating to at least one service; and a protocol data unit generator for generating a protocol data unit containing a header part and a payload part for the uplink packet data service, receiving packet data outputted from the priority queues, inserting the scheduling information into the header part, inserting packet data into the payload part, and transmitting the protocol data unit.

[0027] In order to accomplish the aforementioned objects, according to yet a further aspect of the present, there is provided a Node B for scheduling an uplink packet data service from a user equipment in a mobile communication system, the Node B including a reception unit for a protocol data unit containing a header part and a payload part for the uplink packet data service; a header detection unit for detecting scheduling information for the uplink packet data service from the header part of the protocol data unit and detecting packet data from the payload part of the protocol data unit; a scheduler for generating scheduling assignment information for the uplink packet data service according to the scheduling information; and a transmission unit for transmitting the scheduling assignment information to the user equipment.

BRIEF DESCRIPTION OF THE DRAWINGS

[0028] The above and other objects, features and advantages of the present invention will be more apparent from the following detailed description taken in conjunction with the accompanying drawings, in which:

[0029] FIG. 1A is a view showing variations of an uplink radio resource of a Node B when a Node B control scheduling is not used;

[0030] FIG. 1B is a view showing variations of an uplink radio resource of a Node B when a Node B control scheduling is used;

[0031] FIG. 2 is a view illustrating a UE and a Node B performing uplink packet transmission;

[0032] FIG. 3 is a view showing information exchanged between a UE and a Node B in order to perform uplink packet transmission;

[0033] FIG. 4 is a view showing the types of data transmitted from a UE to a Node B for an uplink packet data service;

[0034] FIG. 5 is a view showing a structure of a logical layer of a UE according to a preferred embodiment of the present invention;

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

[0045] Hereinafter, a preferred embodiment according to the present invention will be described with reference to the accompanying drawings. In the following description of the present invention, a detailed description of known functions and configurations incorporated herein will be omitted when it may make the subject matter of the present invention unclear.

[0046] A Universal Mobile Telecommunication Service (hereinafter, referred to as a UMTS), one of the 3rd Generation Partnership Project (3GPP) mobile communication services, is based on a communication standard of a Global System for Mobile Communication (hereinafter, referred to as a GSM) and a General Packet Radio Service (GPRS) employs a wideband CDMA technology, in contrast to the GSM employing a Time Division Multiple Access (TDMA). A UMTS Terrestrial Radio Access Network (hereinafter, referred to as a UTRAN) includes Node Bs containing a

plurality of cells and a Radio Network Controller (hereinafter, referred to as a RNC) managing radio resources of the Node Bs.

[0047] An interface between a UE and a RNC is called an Uu interface and is classified as a control plane for exchanging control and signaling signals and a user plane for transmitting data traffic. The control plane includes a radio resource control (RRC) layer, a radio link control (RLC) layer, a media access control (MAC) layer, and a physical (hereinafter, referred to as a PHY) layer. Further, the user plane includes a packet data control protocol (PDCP) layer, an RLC layer, a MAC layer, and a PHY layer. Herein, the PHY layer is located in each cell and the layers between a MAC layer and a RRC layer are located in a RNC.

[0048] Particularly, a portion related to a user plane in a MAC layer is called a MAC-d and a portion related to a control plane is called a MAC-c. User data to be transmitted through a dedicated transport channel is generated into a transmission block having a desired size through a MAC-d layer. When the user data is transmitted through an EUDCH, the transmission block passes through a MAC-eu portion in the MAC layer. A MAC-eu layer performs a process a Node B control scheduling, HARQ, etc., for an EUDCH before transmitting data sent from a MAC-d layer to a PHY layer.

[0049] FIG. 5 is a view showing a structure of a MAC-eu layer of a UE transmitting an EUDCH according to a preferred embodiment of the present invention.

[0050] The MAC-eu layer 500 of the UE includes a priority queue distributor 502 and a priority queues (PQs) 504, and receives data to be transmitted to a Node B from a MAC-d layer 518. The received data is sent to the priority queue distributor 502 of the MAC-eu layer 500. The priority queue distributor 502 determines a priority for the received data and buffers the data in a priority queue, which corresponds to the determined priority, from among the priority queues 504.

[0051] The priority queues 504 are used in storing data according to a priority of a service to be provided and have inherent queue identifiers (hereinafter, referred to as QIDs) respectively. That is, each of the priority queues 504 is related to at least one service and stores data having different priorities. FIG. 5 shows two priority queues 504, but the number of the priority queues 504 is randomly determined by a MAC control signal 516 according to the type and number of services being provided. That is, when a priority for data to be transmitted to the Node B is classified as multiple steps, the number of the priority queues 504 increases. The priority is determined according to a transmission time point (i.e., required delay) at which data is to be transmitted to the Node B. That is, data which must be transmitted to the Node B within a rapid time period has a high priority, and data which does not have the necessity of being transmitted to the Node B within a rapid time period has a low priority.

[0052] The priority queue distributor 502 determines a priority for the received data and sends the data to one of the priority queues 504 according to the determined priority. In this way, data having the same priority is sent to the same priority queue. The priority queues 504 store the received data before a resource is assigned by the scheduling of the Node B.

[0053] In order to request a scheduling assignment from the Node B, the MAC-eu layer 500 transmits scheduling information, which contain a buffer status representing the amount of the data stored in the priority queues 504 and a channel status representing the transmission quality of an uplink, through an EUDCH related uplink 510. When the Node B transmits scheduling assignment information to the UE through an EUDCH related downlink 514, a Transport format combination (hereinafter, referred to as a TFC) selection part 508 determines a TFC by means of the scheduling assignment information, reads the data from the priority queues 504 by means of the determined TFC, and transmits the read data through an EUDCH 512. Herein, the UE first transmits data having a high priority stored in the priority queues 504. Therefore, a transmission time can be differently designated according to the priority. Meanwhile, an HARQ entity 506 interprets an ACK/NACK received through the related downlink 514 with respect to the transmitted data, discards data stored in a corresponding priority queue when an ACK is received, and retransmits data stored in a corresponding priority queue when a NACK is received.

[0054] FIG. 6 is a view illustrating an operation by which two UEs request a scheduling assignment to a Node B according to one embodiment of the present invention.

[0055] In FIG. 6, the UE 610 includes two priority queues 612 and 614 and the UE 620 includes one priority queue 622. The priority queue 612 of the UE 610 has a priority higher than that of the priority queue 614, and the priority queue 622 of the UE 620 has the same priority as that of the priority queue 612 of the UE 610. The priority queue 612 of the UE 610 stores 100 bits of data, the priority queue 614 of the UE 610 stores 300 bits of data, and the priority queue 622 of the UE 620 stores 300 bits of data. The Node B 600 has a radio resource capable of receiving only 450 bits of data.

[0056] Referring to FIG. 6, the UEs 610 and 620 transmit buffer status information 630 and 632 representing the amount of data to be transmitted to the Node B 600. That is, the UE 610 transmits the buffer status information 630 corresponding to 400 bits to the Node B 600, and the UE 620 transmits the buffer status information 632 corresponding to 300 bits to the Node B 600. Herein, when uplink channel conditions of the UEs 610 and 620 are identical to each other, the Node B 600 transmits scheduling assignment information 640, which enables only 200 bits to be transmitted, to the UE 610, and scheduling assignment information 642, which enables only 150 bits to be transmitted, to the UE 620.

[0057] The UE 610 determines a TFC by means of the scheduling assignment information 640, transmits data through an EUDCH by means of the determined TFC. That is, according to a priority, 100 bits of data on standby in the priority queue 612 are first transmitted, and then 100 bits of data on standby in the priority queue 614 are transmitted. The UE 620 also determines a TFC by means of the scheduling assignment information 642, transmits data through an EUDCH by means of the determined TFC. That is, 150 bits of data on standby in the priority queue 622 are transmitted.

[0058] Herein, although the priority queue 612 of the UE 620 has a priority higher than that of the priority queue 614

of the UE 610, all data in the standby state are not transmitted. That is, when there exists one UE requesting the scheduling assignment information to the Node B 600, data in the standby state are transmitted according to priority. However, when there exists two or more UEs requesting the scheduling assignment information to the Node B 600, there occurs a problem in that data having a higher priority are transmitted later than data having a low priority.

[0059] FIG. 7 is a view illustrating a preferred embodiment of the present invention for solving the problem in FIG. 6. In FIG. 7, UEs 710 and 720 transmit not only the amount of data but also information on a priority to a Node B 700 at the same time.

[0060] Referring to FIG. 7, the UE 710 includes two priority queues 712 and 714 and the UE 720 includes one priority queue 722. The priority queue 712 of the UE 710 has a priority higher than that of the priority queue 714, and the priority queue 722 of the UE 720 has the same priority as that of the priority queue 712 of the UE 710. The priority queue 712 of the UE 710 stores 100 bits of data, the priority queue 714 of the UE 710 stores 300 bits of data, and the priority queue 722 of the UE 720 stores 300 bits of data.

[0061] The UEs 710 and 720 transmit buffer status information 730 and 732 containing the amount of data to be transmitted and information on a priority to the Node B 700. That is, the UE 710 transmits the buffer status information 730 containing the amount of data corresponding to 400 bits and a QID representing a priority to the Node B 700. That is, the buffer status information 730 signifies that the amount of data corresponding to a Priority 1 is 100 bits and the amount of data corresponding to a Priority 2 is 300 bits. Further, the UE 720 transmits the buffer status information 732 containing the amount of data corresponding to 300 bits and a QID representing a priority to the Node B 700. Herein, when uplink channel conditions of the UEs 710 and 720 are identical to each other, the Node B 700 transmits scheduling assignment information 740 and 742 to the UEs 710 and 720 in consideration of the priority. That is, the Node B 700 transmits scheduling assignment information 740, which enables only 100 bits to be transmitted, to the UE 710, and scheduling assignment information 742, which enables only 250 bits to be transmitted, to the UE 720.

[0062] The UE 710 determines a TFC by means of the scheduling assignment information 740, transmits data through an EUDCH by means of the determined TFC. That is, 100 bits of data on standby in the priority queue 712 are transmitted according to priority. The UE 720 also determines a TFC by means of the scheduling assignment information 742, transmits data through an EUDCH by means of the determined TFC. That is, 250 bits of data on standby in the priority queue 722 are transmitted. In this way, the UEs 710 and 720 can first transmit data having a high priority.

[0063] FIG. 8 is a view showing a structure of a MAC-eu scheduling controller of a UE according to a preferred embodiment of the present invention.

[0064] Referring to FIG. 8, the scheduling controller 800 includes a configuration controller 804, a priority queue (PQ) controller 802, and a TFC selector 806. The priority queue controller 802 receives buffer payload information 810 and 812 from priority queues, and the buffer payload information 810 and 812 represent the amount of data on

standby in each priority queue. In FIG. 8, it is assumed that N number of priority queues exist. The buffer payload information 810 represents buffer payload information sent from a priority queue 1 and the buffer payload information 812 represents buffer payload information sent from a priority queue n. Further, the priority queue controller 802 receives queue information 814 from the configuration controller 804. Herein, the queue information 814 is configuration information of priority queues, and it is related to the sizes and the number of memories of priority queues.

[0065] The priority queue controller 802 transmits a buffer status information 826 containing a QID regarding a priority of a corresponding buffer payload information 810 and 812 to the Node B through an EUDCH tx part 828.

[0066] The TFC selector 806 receives scheduling assignment information 820 through a shared control channel for EUDCH (E-SCCH), a buffer status information 816 about priority queues from the priority queue controller 802, and scheduling configuration information from the configuration controller 804. The scheduling configuration information contains priorities of priority queues, transport format combination set, etc. The TFC selector 806 determines a TFC by means of the buffer status information 816 and the scheduling assignment information 820. The TFC is determined so that data stored in a priority queue having a high priority is first transmitted.

[0067] The TFC selector 806 transmits the determined TFC to a dedicated physical data channel for EUDCH (hereinafter, referred to as a E-DPDCH) tx part 824. The E-DPDCH tx part 824 transmits EUDCH packet data by means of the received TFC. Herein, the determined TFC is transmitted to a dedicated physical control channel for EUDCH (hereinafter, referred to as a E-DPCCH) tx part 822. The E-DPCCH tx part 822 transmits control information containing the TFC together with the EUDCH packet data at the same time point. Also, the TFC is transmitted to the priority queue controller 802 over a scheduling information 818. The priority queue controller 802 understands by means of the TFC the priority queue in which transmitted data has been in a standby state by means of the TFC, and renews the buffer status of the priority queues.

[0068] FIG. 9 is a flowchart illustrating an operation of a MAC-eu scheduling controller according to a preferred embodiment of the present invention.

[0069] Referring to FIG. 9, in step 900, the scheduling controller determines whether or not new data has arrived at priority queues by buffer payload information sent from priority queues. Further, the scheduling controller determines a priority queue from which the buffer payload information has been transmitted, thereby understanding the amount and priority of data transmitted to the priority queues. When the new data has arrived at the priority queues, step 902 is performed. In contrast, when the new data has not arrived at the priority queues, the process returns to step 900.

[0070] In step 902, the scheduling controller transmits buffer status information containing the buffer payload information and buffer status information containing a QID representing a priority relating to the buffer payload information to a Node B.

[0071] In step 904, the scheduling controller determines whether or not scheduling assignment information is

received from the Node B. The scheduling assignment information contains information on a maximum data rate capable of being used by a UE and a permission timing. From the result of the determination, when the scheduling assignment information has been received from the Node B, step 906 is performed. In contrast, when the scheduling assignment information has not been received from the Node B, the process returns to step 904.

[0072] In step 906, the scheduling controller determines a TFC within a data rate assigned by the scheduling assignment information. In determining the TFC, the scheduling controller enables data having a high priority to be first transmitted in consideration of the priority of the data transmitted to the priority queues. In step 908, the scheduling controller controls the data transmitted to the priority queues to be transmitted by means of the determined TFC. The MAC-eu layer generates a MAC-eu protocol data unit (PDU) containing data read from a corresponding priority queue by the control command of the scheduling controller, and transmits the generated MAC-eu PDU through the E-DPDCH. Further, the scheduling controller transmits the determined TFC through the E-DPDCH, and renews information on the changed buffer status. The renewed buffer status is transmitted through an EUDCH.

[0073] FIG. 10 is a view illustrating a MAC-eu signaling between a UE and a Node B according to a preferred embodiment of the present invention. As shown in FIG. 10, the MAC-eu layer 1000 of the UE transmits a buffer status message to the MAC-eu layer 1002 of the Node B. The buffer status information contains a QID and a buffer payload of a priority queue as described above.

[0074] FIG. 11 is a view showing a construction of a MAC-eu PDU containing buffer status information according to a preferred embodiment of the present invention. As shown in FIG. 11, the MAC-eu PDU includes a MAC-eu header 1100 contained in a header part and a plurality of MAC-eu service data units 1102 (SDUs) contained in a payload part. Information contained in the MAC-eu header 1100 is as follows:

[0075] A version flag (VF) representing the version of a MAC-eu PDU format.

[0076] A QID identifying of a priority queue from which a MAC-eu SDU is outputted, constructed of 3 bits.

[0077] A transmission sequence number (TSN) for realigning a MAC-eu SDU according to a priority, constructed of 5 to 6 bits.

[0078] An SID_k representing the size of MAC-d SDUs belonging to an xth MAC-eu SDU set from among the sets of the MAC-d SDUs constituting a MAC-eu PDU, constructed of 2 to 3 bits.

[0079] An N_k representing the number of MAC-d PDUs belonging to a MAC-eu SDU set, constructed of 7 bits.

[0080] A flag (F). When flag (F) is set to 1, the next field is a MAC-eu PDU. When F (flag) is set to 0, the next field is an SID.

[0081] A QID map representing an identifier of a priority queue in which data exists, and a bit number is assigned for as many as the number of priority queues. A numeral 1 represents existence of data and a numeral 0 represents absence of data.

[0082] A buffer payload represents the size of data stored in priority queues in which the value of the QID map is 1, and a bit number according to the length of the QID map is assigned.

[0083] FIG. 12 is a view showing a structure of a MAC-eu scheduler of a Node B according to a preferred embodiment of the present invention.

[0084] Referring to FIG. 12, the scheduler 1200 includes a UE status analyzer 1202 and a resource controller 1204. The UE status analyzer 1202 receives buffer status messages and channel status messages 1210, 1212, and 1214 of UEs UE#1 to UE#N located in a cell area managed by the Node B. The UE status analyzer 1202 receives buffer status information according to a priority queue contained in a MAC-eu header of a MAC-eu PDU transmitted from each UE and estimates the amount of data stored in a priority queue of each UE. Further, the UE status analyzer 1202 transmits an estimated value for the amount of data in each UE to the resource controller 1204.

[0085] The resource controller 1204 calculates an ROT to be assigned to a specific UE in consideration of the estimated value for the amount of data in each UE, the channel status, and a target ROT provided from an RNC through a Node B application protocol (NBAP), and determines a maximum allowed data rate to be assigned to the UE in consideration of the priorities of the priority queues of the UE. Further, when the TFC is determined, the size of data which can be transmitted from the UE and an offset of transmission power are determined according to the TFC. The maximum allowed data rate to be assigned to the UE is contained in maximum allowed TFC information 1220 and 1222 and then transmitted to the UE by E-SCCH tx parts 1224 and 1226.

[0086] FIG. 13 is a flowchart showing an operation of a MAC-eu scheduler of a Node B according to a preferred embodiment of the present invention.

[0087] Referring to FIG. 13, in step 1300, the scheduler determines whether or not a MAC-eu PDU containing scheduling information has been received from a UE. The scheduling information contains buffer payload information of each UE and information on a priority of each buffer. From the result of the determination, when the scheduling information has been received, step 1302 is performed. In contrast, when the scheduling information has not been received, the process returns to step 1300.

[0088] In step 1302, the scheduler determines a maximum allowed data rate to be assigned to the UE on the basis of the buffer status information and the channel status information received from the UE. The maximum allowed data rate is determined in consideration of the target ROT provided from the RNC and a priority of data to be transmitted by the UE. Further, the maximum allowed data rate is transmitted to the UE through a control channel relating to an EUDCH in step 1304.

[0089] FIG. 14 is a block diagram illustrating an apparatus for performing a transmission/reception operation by a UE according to a preferred embodiment of the present invention. First, an operation of a reception side receiving scheduling assignment information will be described.

[0090] Referring to FIG. 14, a signal received in an antenna passes through a radio frequency (RF) unit 1442, is

converted into a baseband signal, and then is inputted to a descrambler **1400**. The descrambler **1400** descrambles the baseband signal by a scrambling code $S_{dl,n}$. The descrambled signal is sent to a despreader **1402**. In order to perform dechannelization for the descrambled signal, the despreader **1402** multiplies the descrambled signal by a channelization code C_{es} , and sends the dechannelized signal to a demodulation unit **1404**. The dechannelized signal is demodulated by the demodulation unit **1404** and decoded by a decoding unit **1406**. Then, an E-SCCH detection unit **1408** detects the scheduling assignment information from the decoded signal, and the scheduling assignment information contains maximum allowed TFC information **1410** assigned to the UE.

[0091] The maximum allowed TFC information **1410** is transmitted to a MAC-eu scheduling controller **1412** and the MAC-eu scheduling controller **1412** determines a TFC by means of the maximum allowed TFC information **1410**. The TFC is determined considering information on a priority of data on standby in priority queues **1422** and **1424**. For this reason, the priority queues **1422** and **1424** store data relating to one or more services having different priorities, and transmit a QID and buffer payload information to the MAC-eu scheduling controller **1412** periodically or whenever new data is stored. The MAC-eu scheduling controller **1412** transmits information on the determined TFC to an E-DPCCH generator **1414**. The E-DPCCH generator **1414** generates a control signal containing other control information and the TFC. The generated control signal is coded by a coding unit **1416** and the coded signal is modulated by a modulation unit **1418**. Then, the modulated signal is subjected to channelization by a spreader **1420** with a channelization code C_{ec} and then is transmitted to a multiplexer **1438**.

[0092] A MAC-eu PDU generator **1428** performs two functions. First, the MAC-eu PDU generator **1428** includes the QID and the buffer status information sent from the MAC-eu scheduling controller **1412** into a MAC-eu header. Secondly, the MAC-eu PDU generator **1428** appends the MAC-eu header to the data on standby in the priority queues **1422** and **1424** by means of the TFC sent from the MAC-eu scheduling controller **1412**, and generates a MAC-eu PDU. The MAC-eu PDU is coded by a coding unit **1430** and rate-matched by a rate matching unit **1432**. The rate-matched signal is modulated by a modulation unit **1434** and the modulated signal is subjected to channelization by a spreader **1436** with a channelization code C_c . The channel coded data is transmitted to multiplexer **1438**. The multiplexer **1438** multiplexes signals provided from the spreaders **1420** and **1436** and signals from other channels. The multiplexed signal is scrambled by a scrambler **1440** with a scrambling code $S_{dpch,n}$ and is converted into an RF signal by an RF unit **1444**. Then, the RF signal is transmitted to the Node B through an antenna.

[0093] FIG. 15 is a block diagram illustrating an apparatus for performing a transmission/reception operation by a Node B according to a preferred embodiment of the present invention. First, an operation of a reception side receiving scheduling information will be described. The reception part of the Node B has N number of reception paths **1540** and **1542** corresponding to each of N number of UEs performing an uplink packet data service. Herein, an operation of the reception path **1540** corresponding to a UE#1 will be

described, but it is apparent to those who skilled in the art that the other reception paths also perform the same operations.

[0094] Referring to FIG. 15, a signal received in an antenna passes through an RF unit **1538**, is converted into a baseband signal, and then is inputted to a descrambler **1518**. The descrambler **1518** descrambles the baseband signal by a scrambling code $S_{dpch,n}$. The descrambled signal is sent to despreaders **1520** and **1522** and then is dechannelized into an E-DPCCH signal and an E-DPDCH signal. The E-DPCCH signal for which channelization has been performed by the despreader **1522** with a channelization code C_{ec} is demodulated by a demodulation unit **1524**, and then is decoded by a decoding unit **1526**. A control information detector **1527** detects control information necessary in receiving EUDCH data from data decoded by the decoding unit **1526**, and the control information contains modulation information, etc., of the EUDCH data.

[0095] The E-DPDCH signal for which channelization has been performed by the despreader **1520** with a channelization code C_c is demodulated by a demodulation unit **1528** with the modulation information detected by the control information detection unit **1527**. The demodulated signal is subjected to a rate-dematching by a rate-dematching unit **1530** and then is decoded by a decoding unit **1532**.

[0096] A MAC-eu header detection unit **1534** separates buffer status information in a header and data in a payload from a MAC-eu PDU sent from the decoding unit **1532**. Herein, when a QID map in a MAC-eu header has values other than 0, the MAC-eu header detection unit **1534** detects buffer status information **1516** contained in the MAC-eu header to transmit the detected buffer status information **1516** to a MAC-eu scheduler **1514**. Herein, the buffer status information **1516** includes at least one QID and buffer payload information. Further, the MAC-eu header detection unit **1534** separates MAC-eu SDUs, except for the MAC-eu header, from the MAC-eu PDU and transmits the MAC-eu SDUs to reordering buffers of an upper layer. The reordering buffers are located in an RNC, correspond to priority queues of a UE-side, and align received MAC-eu SDUs according to TSNs of the MAC-eu SDUs.

[0097] The MAC-eu scheduler **1514** generates a maximum allowed TFC information **1512** for each UE by means of the buffer status information **1516** and other scheduling information, and transmits the generated maximum allowed TFC information **1512** to an E-SCCH generator **1510**. The maximum allowed TFC is determined considering a priority of data contained the buffer status information to be transmitted. The E-SCCH generator **1510** generates scheduling assignment information for the maximum allowed TFC information **1512**. The scheduling assignment information is coded by a coding unit **1508** and then is modulated by a modulation unit **1506**. The signal modulated by the modulation unit **1506** is subjected to channelization by a spreader **1504** with a channelization code C_{es} , and then is transmitted to a multiplexer **1502**. The multiplexer **1502** multiplexes the received signal together with other downlink channel signals. The multiplexed signal is scrambled by a scrambler **1500** with a scrambling code $S_{dl,n}$ and is converted into an RF signal by an RF unit **1536**. Then, the RF signal is transmitted to a UE through an antenna.

[0098] As described above, in the present invention, when a UE transmits data having required different priorities

through an enhanced uplink channel at the same time, a Node B control scheduling reflects the priorities of the data. For this, the UE transmits buffer status information of a priority queue corresponding to quality of service, and a Node B can perform scheduling by means of the received buffer status information of the priority queue. Accordingly, the present invention provides a differentiated service according to required priorities, thereby satisfying the requirements of users.

[0099] While the invention has been shown and described with reference to certain preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention as defined by the appended claims.

What is claimed is:

1. A method for reporting a status of a buffer storing packet data to be transmitted by a user equipment (UE) for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the method comprising the steps of:

- a) storing packet data having a priority corresponding to a plurality of priority queues relating to at least one service; and
- b) transmitting buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues.

2. The method as claimed in claim 1, wherein, in step b), the buffer status information is inserted into a header part of a protocol data unit (PDU) for the uplink packet data service and the packet data is inserted into a payload part of the protocol data unit, and then the protocol data unit is transmitted.

3. The method as claimed in claim 2, wherein the buffer status information includes:

a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;

an identifier of at least one priority queue represented by the queue identifier map; and

a size of the data stored in at least one priority queue represented by the queue identifier map.

4. The method as claimed in claim 2, wherein the header part is a media access control (MAC) signaling header for an enhanced uplink dedicated channel (EUDCH).

5. The method as claimed in claim 1, further comprising a step of receiving scheduling assignment information corresponding to the buffer status from a Node B providing the service to the user equipment, first reading packet data having a high priority from the priority queues according to the scheduling assignment information, and transmitting the read packet data.

6. A method which enables a user equipment to report scheduling information for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the method comprising the steps of:

generating a protocol data unit including a header part and a payload part for the uplink packet data service; and

inserting the scheduling information into the header part, inserting packet data for the uplink packet data service into the payload part, and transmitting the protocol data unit.

7. The method as claimed in claim 6, wherein the scheduling information contains queue identifiers representing a plurality of priority queues having inherent priorities and relating to at least one service, and buffer payload information representing an amount of packet data stored in the priority queues.

8. The method as claimed in claim 7, wherein the buffer payload information includes:

a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;

an identifier of at least one priority queue represented by the queue identifier map; and

a size of the data stored in at least one priority queue represented by the queue identifier map.

9. The method as claimed in claim 6, wherein the header part is a media access control signaling header for an enhanced uplink dedicated channel.

10. The method as claimed in claim 7, further comprising a step of receiving scheduling assignment information corresponding to the scheduling information from a Node B providing the service to the user equipment, and first transmitting packet data having a high priority according to the scheduling assignment information.

11. An apparatus for reporting a status of a buffer storing packet data to be transmitted by a user equipment for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the apparatus comprising:

a plurality of priority queues having same priorities, for storing packet data relating to at least one service;

a scheduling controller for generating buffer status information containing queue identifiers of the priority queues and buffer payload information representing an amount of the packet data stored in the priority queues; and

transmission unit for transmitting the buffer status information.

12. The apparatus as claimed in claim 11, wherein the transmission unit comprises a protocol data unit generator for generating a protocol data unit containing a header part and a payload part for the uplink packet data service, inserting the buffer status information into the header part, and inserting packet data read from the priority queues into the payload part.

13. The apparatus as claimed in claim 12, wherein the buffer status information includes:

a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;

an identifier of at least one priority queue represented by the queue identifier map; and

a size of the data stored in at least one priority queue represented by the queue identifier map.

14. The apparatus as claimed in claim 12, wherein the header part is a media access control signaling header for an enhanced uplink dedicated channel.

15. The apparatus as claimed in claim 11, wherein the scheduling controller receives scheduling assignment information corresponding to the buffer status from a Node B providing the service to the user equipment, and controls the priority queues to first output packet data having a high priority according to the scheduling assignment information.

16. An apparatus which enables a user equipment to report scheduling information for a scheduling assignment of an uplink packet data service in a mobile communication system supporting the uplink packet data service, the apparatus comprising:

- a plurality of priority queues having same priorities, for storing packet data relating to at least one service; and
- a protocol data unit generator for generating a protocol data unit containing a header part and a payload part for the uplink packet data service, receiving packet data outputted from the priority queues, inserting the scheduling information into the header part, inserting packet data into the payload part, and transmitting the protocol data unit.

17. The apparatus as claimed in claim 16, wherein the scheduling information contains queue identifiers representing the priority queues having inherent priorities and relating to at least one service, and buffer payload information representing an amount of packet data stored in the priority queues.

18. The apparatus as claimed in claim 17, wherein the scheduling information includes:

- a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;
- an identifier of at least one priority queue represented by the queue identifier map; and
- a size of the data stored in at least one priority queue represented by the queue identifier map.

19. The apparatus as claimed in claim 16, wherein the header part is a media access control signaling header for an enhanced uplink dedicated channel.

20. The apparatus as claimed in claim 17, further comprising a scheduling controller for receiving scheduling

assignment information corresponding to the scheduling information from a Node B providing the service to the user equipment, and controlling the priority queues to first output packet data having a high priority according to the scheduling assignment information.

21. A Node B apparatus for scheduling an uplink packet data service from a user equipment in a mobile communication system, the Node B comprising:

- a reception unit for a protocol data unit containing a header part and a payload part for the uplink packet data service;
- a header detection unit for detecting scheduling information for the uplink packet data service from the header part of the protocol data unit and detecting packet data from the payload part of the protocol data unit;
- a scheduler for generating scheduling assignment information for the uplink packet data service according to the scheduling information; and
- a transmission unit for transmitting the scheduling assignment information to the user equipment.

22. The Node B apparatus as claimed in claim 21, wherein the scheduling information contains queue identifiers representing the priority queues having inherent priorities and relating to at least one service, and buffer payload information representing an amount of packet data stored in the priority queues.

23. The Node B apparatus as claimed in claim 22, wherein the payload information includes:

- a queue identifier map representing at least one priority queue, in which the stored data exists, from among the priority queues;
- an identifier of at least one priority queue represented by the queue identifier map; and
- a size of the data stored in at least one priority queue represented by the queue identifier map.

24. The Node B apparatus as claimed in claim 21, wherein the header part is a media access control signaling header for an enhanced uplink dedicated channel.
